OFFICE OF TAX AND REVENUE REAL PROPERTY TAX ADMINISTRATION INTEROFFICE MEMORANDUM

TO: REAL PROPERTY ASSESSMENT DIVISION FROM: DAVID W. FITZGIBBON, CHIEF APPRAISER SUBJECT: TAX YEAR 2010 REASSESSMENT EFFORT

DATE: 2/19/2009

Let me begin by offering my thanks to the Assessment Division Staff for their contributions to the Tax Year 2010 valuation program. But more than thanks I should also offer congratulations on achieving what at times seemed like an impossible task. Never before in my memory has there been a more difficult time to produce accurate, uniform assessments while keeping in mind the effect our values will have on the taxpayers. The empathy our staff has shown toward the taxpayer has been a heavy weight on our shoulders counterbalanced by the professionalism and integrity demonstrated by the staff

While all around us, from every media report and news article we were told the sky was falling, the staff stayed on course and through diligent research and analysis were able to separate fact from fiction and produce values that accurately reflect what the buyers and sellers of property within the District were really doing. The market conditions within the District, while truly affected by the national crisis, have not experienced the drastic downturns that some of our surrounding areas have suffered. DC is still standing tall comparatively speaking with foreign investors seeing us as a market for real estate investment greater than most other top markets.

The challenges faced by the staff were tremendous. Foreclosures are at an all time high. Lending institutions are going bankrupt and credit has tightened to the point that projects are being abandoned or put on hold. To make our task even more difficult, most of the dramatic downturn happened within the last quarter of 2008. Had we relied on the entire year's data, the statistical analysis made it appear that we had totally escaped the problems facing other jurisdictions. Sales and incomes were strong at the first part of the year and virtually non-existent toward the end. Both the Residential and Commercial Assessment Units went above and beyond normal procedures in researching the most up to the minute data to predict what the state of the market would be as of January 1st, our

valuation date. The resulting values are in my opinion truly reflective of Fair Market Value as of our appraisal date.

The difficult task remains to defend these values with the factual data utilized in the preparation of the values and separate the emotion from the reality. The public tends to believe what they hear or see in the media, and according to the media, times are bad. It is up to us to point out the differences in the market conditions in the surrounding areas that have truly taken a beating and within the District where we have fared much better. It goes without saying that we have great respect for the taxpayers and their opinions and we should expect the fears and concerns to be put forth in greater numbers than ever. I have great confidence in the professionalism and ethics of our staff and in their ability to thoroughly explain the process to the public throughout the appeals season.

RPAD has continued to develop and utilize modern technology to assist us in the gathering and processing of information. Online services will aid both us and the public in obtaining data for comparison and equalization of values. With this year's total parcel count topping 194,000, the use of modern technology has become a necessity instead of a desirable tool. We encourage everyone, within RPAD as well the public, to utilize all available resources in the review of this year's values.

Explanation of Residential Market-oriented Cost Method

Note: The market-oriented cost approach to valuation is further explained and illustrated in the document, *Vision Residential Valuation Process*.

The market-oriented cost approach involved the following:

- 1. Extracting the CAMA data from approximately 9,900 qualified sales and importing it into SPSS.
- 2. Building a preliminary regression model that reflects the variables of the CAMA cost approach.
- 3. Reviewing the results of the preliminary regression to identify candidate market areas where the data was such to allow for successful regression analysis.
- 4. Eliminating outliers in the candidate areas to better ensure accuracy of the regression results.
- 5. Establishing time adjustment factors in order to analyze sale prices as of a specific point in time. The city was divided into 4 major market areas for time adjusting sale prices. Market data indicated monthly time adjustment factors over 33+ months (1/1/2006 through 10/9/2008) as follows:

	1/1/06 -	1/1/07 -	1/1/08 —
	12/31/06	12/31/07	9/30/08
"Southeast" Neighborhoods (2, 3, 16, 18, 22, 28, 32, 33, 43)	+ 0.50% /mo	+ 0.10% /mo	- 0.70% /mo
"Northeast" Neighborhoods (5, 6, 7, 12, 14, 15, 17, 19, 31, 35, 36, 42, 47, 48, 49, 51, 52, 56, 66)	+ 0.10% /mo	0.00% /mo	- 1.10% /mo
"Northwest" Neighborhoods (1, 4, 8, 11, 13, 21, 23, 24, 25, 26, 27, 29, 30, 34, 37, 38, 41, 50, 53, 54, 55)	+ 0.20% /mo	+ 0.10% /mo	0.00% /mo
"Downtown" Neighborhoods (9, 10, 20, 39, 40, 46)	+ 0.10% /mo	+ 0.10% /mo	- 0.60% /mo

- 6. Building a final regression model, using the time-adjusted sale price as the dependant variable.
- 7. Calibrating that model using non-linear multiple regression. Variables were included to extract land values from the market.
- 8. Reviewing the regression predicted values and removing extreme outliers.
- 9. Examining the predicted-values-to-time-adjusted-sale-price ratios for equitability with respect to lot size, building area, age, use, grade, and location.
- 10. Entering the coefficients indicated by the regression analysis back into the CAMA program's cost model.
- 11. Applying the cost model in CAMA and reviewing the resulting values to ensure they agreed with the predicted values produced by the regression.
- 12. Performing sales analysis to determine if acceptable levels of assessment were achieved and adjusting rates as necessary.
- 13. Applying model to inventory and producing old-to-new (outlier) reports and percent change detail analysis reports for assessor review.
- 14. Incorporating oversight of the computer aided procedure by our professional staff cited in the <u>2010 Valuation Review Process</u>. All projected market value changes are submitted to the staff for their review, refinement, and adjustments.

Explanation of Residential Condominium Valuation Methods

Regression:

The sales comparison approach using multiple regression analysis involved the following:

- 1. Extracting the CAMA data of qualified sales and importing it into SPSS.
- Reviewing data to determine what regimes were candidates for regression analysis. As a rule, regimes could be valued using regression where the physical data attributes were complete and adequate sales data existed. Regimes without adequate sales, but with complete data, could be clustered with regimes having similar profiles to allow regression to be used.
- 3. Exploring the data to determine what variables would likely contribute to the model.
- 4. Building a base model.
- 5. Reviewing the results of the base model and eliminating outliers in the candidate regimes to better ensure the accuracy of the regression results.
- 6. Establishing time adjustment factors in order to analyze sale prices as of a specific point in time.
- 7. Building a final regression model, using the time-adjusted sale price as the dependant variable.
- 8. Calibrating that model using multiple regression analysis.
- 9. Applying the model to the sales, reviewing the predicted values and removing extreme outliers.
- 10. Performing sales analysis to determine if acceptable levels of assessment were achieved and adjusting rates as necessary.
- 11. Extracting condominium inventory data and importing into SPSS.
- 12. Applying model to inventory, and exporting the values back to CAMA, allocating 30% of predicted value to land and 70% of predicted values to improvements.
- 13. Producing percent change reports for assessor review.
- 14. Identifying necessary corrections to data and location adjustments.
- 15. Repeating process of extracting data, applying model, and exporting back to CAMA to include corrections.

Final Assessor Review:

At the conclusion of the valuation, several reports are produced showing the results of the reassessment. These reports, reflecting proposed market value changes, are submitted to the assessment staff for their review, refinement and adjustment in accordance with the processes outlined in the <u>2010 Valuation Review Process</u> document.

The Condominium Regression Model:

ESP= (324.02 * SIZE * SIZE_ADJ * EFFIC_ADJ * COND_ADJ * VIEW_ADJ * BATH_ADJ + PARK_ADJ) * LOC_ADJ.

<u>Estimated Sale Price (ESP)</u> – the value predicted by the model for the parcel, given the variables in the model, the coefficients of those variables and the attributes of the subject unit.

Base Rate (324.02) – base size rate (constant)

Size – the square footage of the unit

Size Adj. - the adjustment for the unit's size being larger or smaller than the base size

The base unit size is 800 sf. The formula for calculating the size adjustment is: $((SIZE^{.6904})/SIZE)/.12624$, where .12624 = $(800^{.6904})/800$). See graph titled <u>Condominium Size Curve</u>.

Efficiency Adj. – if the unit is an efficiency unit, a 0.95 adjustment is applied.

Condition - adjustment for the unit's physical condition

(1) Poor	.75
(2) Fair	.87
(3) Average	1.00
(4) Good	1.08
(5) Very Good	1.12
(6) Excellent	1 20

View - adjustment for the unit's view

(1) Poor	.87
(2) Fair	.95
(3) Average	1.00
(4) Good	1.05
(5) Very Good	1.10
(6) Excellent	1.15

Bath Adj. – adjustment for the unit's number of baths more than one.

```
BATH_ADJ = 1 + (((FULLBATH - 1) + (.5 * HALFBATH)) * .08)

Example: 2 \frac{1}{2} baths: 1 + (((2 - 1) + (.5 * 1)) * .08) = 1.112

3 baths: 1 + (((3 - 1) + (.5 * 0)) * .08) = 1.16
```

Parking – adjustment for Limited Common Element parking

<u>Outdoor</u>	<u>Covered</u>	<u>Indoor</u>	
25940	33350	44470	subject to location adjustment

Location - adjustment for unit's geographic location

Location adjustments were made for neighborhood, sub-neighborhood, cluster of regimes, or unique regime. The actual location adjustment for any unit may be the combination of one or more of those location factors.

Explanation of Cooperative Valuation Method

Cooperatives are a type of residential property. In a cooperative, a corporation owns the property and the shareholders can use the unit or units represented by their shares. In Washington, DC, cooperatives are assessed according to statue by either of three methods. The first method is by calculating the cumulative value of the leasehold interests (by sales). The second method is to treat the project as if it was a condominium project and reduce the value by 30%. After arriving at either of these values, we further reduce the value an additional 35% according to the statue. The third method is available only to Limited Equity Cooperatives.

Limited-equity cooperatives (LEC) are defined in the DC official Code in § 47-802 (11) as, "one required by a government agency or non-profit to limit the resale price of membership shares to keep the housing affordable for low and moderate income buyers." The assessed value of the improved real property owned by an LEC is the lesser previously described approaches or the annual amount residents pay in carrying charges (excluding subsidies), divided by an appropriate capitalization rate as determined by the Office of Tax and Revenue (OTR).

For 2010, we reviewed all the complexes with sales information and calculated the sales prices per square foot. No time adjustments were deemed necessary for this period. For previous years matched pairs sales were used to calculate the typical percentage increase per month. We were surprised to discover that in the better complexes the trend from 1999 - 2002 was approximately 3% per month. In other words, units that sold in 1999 would sell for about twice as much in 2002. In 2003 and 2004 the market began to cool although sales prices were still increasing by 1-2% per month in many complexes. Multiplying the square footage of the units by the adjusted rates (occasionally they were adjusted for view or parking as sales indicated) would result in the aggregate values which were further reduced for personal property and the result multiplied by 65%.

In complexes where there were no sales, we treated them as if they were condominiums. To do this we would find a condominium as similar as possible to the subject and use the square foot rate that seemed to be appropriate to the square foot of the units or the estimated square footage. We would multiply the rate times the square footage and reduce the result by 30% and then by 35%. The complexes without sales were usually limited equity coops or very small complexes.

2010 Valuation Review Process

As part of the valuation process, initial assessments for all properties will be estimated and preliminary report will be generated summarizing the results of the valuation effort. Your review, modification and approval of the proposed assessments indicate that they are representative of the estimated market value.

The Valuation Review Process is designed to allow for a thorough review of the new values for the upcoming tax year before notices are sent to property owners.

The purpose of this review is two-fold. First, it allows us the opportunity to correct any errors that may have occurred in the valuation process before they cause administrative difficulties (i.e. public relations problems, unnecessary appeal activity, and the like). Second, the process provides feedback to the CAMA modeling and calibration process.

The process involves examining all assessments with particular attention given to the outliers in a relatively short period of time. As such, the appraiser is primarily concerned with arriving at a reasonable final value estimate for all accounts by focusing attention to the properties on the outlier list, known as the Old-to-New Report. Briefly, the process involves the appraiser of record reviewing a selected group of properties in their neighborhood that, on first inspection, appear to be over or under appraised based on previously determined criteria such as sales price, percent change reports, etc. When this review indicates correct values, no records are changed; however, if the value requires modification, the appraiser will make changes in the CAMA record and on the PRC to correct the situation. If he/she discovers minor discrepancies in the data, it should be noted and corrected or revisited during another inspection program at the discretion of the appraiser. The purpose of this program is not to engage in a detailed analysis of accounts but rather to expeditiously review outlier accounts to improve our estimate of market value.

NOTE: It is advisable that the appraiser has a solid knowledge of CAMA valuation before proceeding with the review process. Please refer to the most current version of the "CAMA Residential Construction Valuation Guideline." Along with the report entitled "VISION CAMA Valuation," the guideline will serve as a tutorial for the methodology employed within CAMA for valuing residential property.

Following are some general guidelines to consider while conducting review activity.

1. The valuation review process begins with CAMA producing two reports for each (sub) neighborhood. The first report is the "Old to New" report that shows the old value, new value, percent and dollar change in value from the current assessment to the proposed assessment for specific properties that constitute outliers in the (sub) neighborhood. Included are the individual PRCs for each corresponding account listed in the report where the proposed value increased 10 percentage points or more above the median percent change for the (sub)

1

neighborhood or decreased 10 percentage points or more below the median percent change. The second report, Percent Change Detail Analysis, contains more specific detail about all of the accounts in the selected (sub) neighborhood.

- 2. The appraiser will be provided these two individual reports for each of the assigned (sub) neighborhoods, along with individual PRCs from the Old-to-New report.
- 3. Before individual reviews of the Old-to-New report begins, the appraiser will examine the Percent Change Detail Analysis report for signs of irregularities or general discrepancies based on their knowledge of their neighborhoods. The review entails several tasks as follows:
 - A. Review the "A/S Ratio", when present. The ratios are calculated based on sales over a long period of time. Pay particular attention to sales that occurred during calendar year 2008. These sales will give a better picture of the most recent assessment/sales ratio reflective of the current market conditions. Where the assessed values are not close to the sales prices, fully examine the record, and consider making appropriate changes. The "VC" flag can be used to indicate that a sale has been previously disqualified, possibly rendering an unusual ratio less meaningful. Additionally the review of the "VC" code with an unusual ratio may indicate that a previously qualified sale needs to be now disqualified.
 - B. Examine the "Grade" of the accounts. If there is a two or more departure of grade between the account and the typical grade in the (sub) neighborhood, the appraiser may be concerned.
 - C. Look for extremes in the "Cond" and "% Good" data. Again, on average, these should be relatively consistent throughout the (sub)neighborhood.

The preferred process to follow when conducting individual reviews of accounts contained on the Old-to-New report (residential only) is as follows:

1. The appraiser will examine each record that appears on the "Old to New" report. Each record has been selected for inclusion because the proposed value decreased 3 percentage points or more below the median percent change for the (sub) neighborhood or increased 10 percentage points or more above the median percent change for the (sub) neighborhood. However, PRCs were printed for records where the proposed value decreased 10 percentage points or more below the median percent change for the (sub) neighborhood or increased 10 percentage points or more above the median percent change for the (sub) neighborhood. As a result, there will probably be more accounts listed on the "Old to New" report than printed PRCs. These records constitute the "outliers" of

the (sub) neighborhood. The values may be correct or erroneous, and the purpose of this process is to make that determination.

- 2. The appraiser, exercising his or her professional skill and judgment, first will conduct a "desk review" of each account appearing on the report. If the value does not seem reasonable perform the following actions:
 - A. Examine the PRC for any missing or incorrectly coded data contained in the Construction Detail section.
 - B. In the Building Summary Section, check the sq. ft. sizes of the areas listed for accuracy and reasonableness.
 - C. Check the Building Cost Section for correct Effective Area, Special Feature RCN and % Good. If any are erroneous, examine their respective sections for details.
 - D. Examine the Special Features/Amenities and Detached Structures sections for accuracy.
 - E. On the front of the PRC, check the Land Line Valuation Section for proper size and value.
 - F. Make use of the Pictometry tool available in the Mobile Video Viewer or the Mapping Apps folder.
- 3. Several results may occur from the desk review:
 - A. The desk review indicates the value is correct. In this case, note in the column adjacent to the account "OK", your initials and the date.
 - B. The desk review indicates an erroneous value discovered by examining various reports and records (i.e. Percent Change, CAMA record, etc). In this case, the appraiser makes the correction in the CAMA record, notes the changes made on the PRC in red, notes on the Old-to-New report the new amount, your initials and the date.
 - C. The desk review is inconclusive and a field inspection is in order.

An example may help illustrate scenario "A", the first situation. Let's say the Old-to-New report indicates an account has jumped 400%, from \$300,000 to \$1,200,000! That amount of increase seems absolutely erroneous. To determine a possible explanation, the appraiser begins the review by locating the account on the Percent Change Detail Analysis report. After finding the account, the appraiser notices that the properties close to the account have only increased by approximately 20%, the median for the neighborhood. They are approximately similar to the account in size, grade, and condition, but their prior year's value was \$900,000, while the outlier was only \$300,000. The appraiser would be safe to conclude that the account was grossly under-assessed last year. The low "old" value caused the large increase in value, not an over-assessed new value. To complete the desk review, the appraiser notes on the Old-to-New report, "OK", his/her initials and the date.

Scenario "B", the second situation, may find the appraiser reviewing an account that also appears to be over-assessed based on the large increase from old to new value. The appraiser again locates the account on the Percent Change Detail Analysis report and reviews the account in context to other (sub)neighborhood properties. The appraiser discovers that most of the data about the account is similar to the other properties – same use code, similar size, percent good, etc. However, where most of the properties are listed at Grade 4, the account is Grade 7. This would help explain the likelihood that the account is over-assessed. The appraiser would make the change to the grade in the CAMA system, note the new value, make the change on the PRC in red, and document the change on the Old-to-New report by writing the new value, his/her initials and the date in the far right column of the report next to the account.

The last scenario, "C", results when the appraiser can not immediately explain the reason an account appears on the Old-to-New report. He/she should set aside accounts that will require field inspection and at a point, go to the field for inspection. Upon conclusion of the inspection, the appraiser will document the results in a similar manner to the desk reviews. The actual schedule for field- work will vary and will be coordinated by the appraiser and his/her supervisor.

Records Retention, Old-to-New Reports (residential only) and Percent Change Detail Analysis Reports (residential, residential condominium, commercial) are to be retained for two years, so that the current and proposed years are readily available for review. The retained reports will reflect all necessary dates and initials, indicating the required review and approval. The supervisor for each unit will be responsible for ensuring compliance with the review process within their unit, and for the retention of their unit's reports for the appropriate period of time. Reports may be discarded when they are no longer the current or proposed year. For example, upon the completion of the tax year (TY) 2010 revaluation, the TY 2008 reports may be discarded, and the reports from TY 2009 (current) and TY 2010 (proposed) must be on file.

Assessment Roll and Property Owner Notification

Upon completion of the annual reassessment and following the detailed final edit by appraisers, the CAMA manager runs a series of edit programs that makes final edits and consistency checks of all accounts. Any problems are returned to appraisers for review or correction. Following corrections, the CAMA Manager completes a final edit and uploads the required information via CAMA extract to the Integrated Tax System.

Annual Assessment Notices to notify property owners may be printed from ITS in batch mode or an extract may be produced for an outside vendor to produce assessment notices.

Market Approach to Land Valuation in Costed Neighborhoods

A non-linear regression model was used to calibrate the residential cost model. It was developed from citywide market analysis of qualified sales. One of the variables calibrated by the model was the land rate. Base land rates were adjusted for location in each subneighborhood. Regression analysis calibrated the land and building components of the model at the same time using the same market data. Additionally, the analysis established three size curves for land area. The three size curves indicate that as lot sizes increase. values also increase. However, with land size curve "3" values increase more rapidly with size as compared to land size curve "2". Land size curve "1" increases at the smallest rate. In all three cases, land rates decrease as land area increases. Market data supports both curves up to approximately 5 times the standard lot size. However, in application, rates are assumed to continue similar decreases beyond that point. Each sub-neighborhood was assigned to one of the three land size curve groups based upon analysis of the qualified sales data. It is important to keep in mind, that land value is only one component of a number of variables that contribute to a property's sale price and/or estimated market value. In practical terms, it is the combination of all of a property's attributes, nuances in the market, and buyer preference that contribute to the final market value of a property. It is difficult to isolate some of the contributory elements and value them separately with certainty. Nevertheless, it is required in the District of Columbia that land and building values be separated for assessment purposes. Because of this requirement, it is necessary to create land rate tables for use in the District's CAMA product. These rates were developed in the regression analysis referred to above. The results of the analysis are applied to the market-oriented cost model in the Vision CAMA system.

Land is calculated in Vision using the following algorithm:

Area * ((Base Rate * Size Adj) + \$ Special Adj 1 + \$ Special Adj 2) * % Special Adj 1 * % Special Adj 2

Where:

Area is the lot size expressed in square feet.

Base Rate is the market-derived rate for each sub-neighborhood.

Size Adj is the market-derived adjustment made for the lot size as it relates to the standard size lot for the sub-neighborhood. The look-up along the size curve is based on the ratio of the subject lot size to the standard lot size.

- % Special Adj is any adjustment present that is expressed and applied as a percentage adjustment to the rate.
- \$ Special Adj is any adjustment present that is expressed and applied as a dollar adjustment to the rate.

Land Rate Development Example

A hypothetical example may help illustrate how regression analysis develops the base land rates and subsequent adjustments to the rates. Suppose two properties in a neighborhood were recently sold. The first, comprised of just a house without land, sold for \$400,000. The second property had the identical house but with a lot of 2,000 square feet (sf.), the typical size for that neighborhood. It sold for \$600,000. In a process similar to adjusting comparables in the sales comparison approach to value, regression analysis identifies the contributory value of the lot to the second property and sets its value to \$200,000. The base land rate of \$100 per sf (\$200,000/2,000 sf) will be the basis for lot values for all other properties in that (sub)neighborhood.

Next, let us assume another house sells. In this instance, the house is identical to the previous sale in all respects, except the lot size was 4,000 sf instead of the "standard" (base lot) size of 2,000 sf. This house recently sold for \$700,000, \$100,000 more than a property with the standard lot size. The land component of this sale is \$300,000.

This sale helps develop size adjustments for non-standard lots in the neighborhood. If no adjustment was made to the land rate, the land component of this sale would be \$400,000 (4,000 sf * \$100). The appraisal would overstate the value of the property by \$100,000. An adjustment to the base land rate is necessary to recognize the market response to the departure from the standard lot size. Regression analysis would calculate the appropriate land size adjustment necessary to properly determine the contributory value of the larger lot. Dividing the market-indicated value of the lot by the unadjusted appraised value of the lot (\$300,000/\$400,000) yields a factor of 0.75. In this example, CAMA would follow the model:

Appraised land value = Area * (Base Rate * Size Adj)

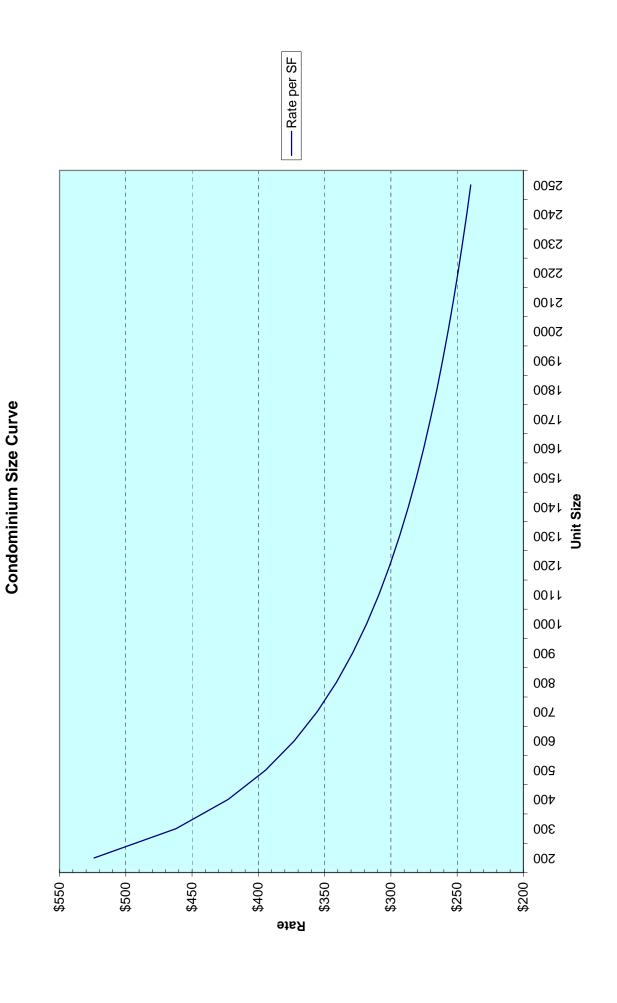

Residential Base Land Rates By Neighborhood

NBHD	Base Lot Size	Base Rate	Base Lot Value	Size Curve
1A	4000 sf	\$90.68	\$362,720	LG1
1B	5000 sf	\$74.24	\$371,200	LG1
1C	5000 sf	\$76.50	\$382,500	LG1
2A	2000 sf	\$68.95	\$137,900	LG1
2B	2000 sf	\$72.73	\$145,460	LG1
3	2000 sf	\$60.46	\$120,920	LG1
4A	6700 sf	\$76.97	\$515,700	LG2
4B	10000 sf	\$61.32	\$613,200	LG2
4C	8000 sf	\$70.58	\$564,640	LG2
5A	1700 sf	\$93.51	\$158,970	LG1
5B	1700 sf	\$86.75	\$147,480	LG1
6A	4000 sf	\$57.66	\$230,640	LG1
6B	4000 sf	\$52.99	\$211,960	LG1
6C	2000 sf	\$93.64	\$187,280	LG1
6D	4000 sf	\$56.45	\$225,800	LG1
6E	3000 sf	\$61.84	\$185,520	LG1
7A	2000 sf	\$84.17	\$168,340	LG1
7B	3000 sf	\$59.78	\$179,340	LG1
7C	3000 sf	\$64.53	\$193,590	LG1
7D	5000 sf	\$40.90	\$204,500	LG1

Residential Land Size Curves

Vision[®] CAMA Residential Valuation Process

he market-derived cost approach to the valuation of real estate follows the generic formula of **Market Value = ((RCN-LD) + land value)**, where **RCN** is Replacement Cost New of the improvements and **LD** means Less Depreciation. When properly developed and calibrated, this approach is a reliable indicator of market value especially suited to mass-appraisal CAMA systems.

The following exercise will attempt to illustrate how the Vision[©] CAMA system utilized by the District of Columbia, calculates values using the above model. The first section will illustrate the development of the Replacement Cost New of a typical residence, the second will show the steps involved in determining the amount of depreciation that has accrued to the residence, and the last section will illustrate land or lot valuation.

Replacement Cost New

The Vision® CAMA system arrives at a RCN value for residential properties based on a market-calibrated hybrid cost model. The hybrid nature of the model simply means that the model employs both additive and multiplicative variables in its design and specification. The nature of the model will become clearer as we proceed through this exercise. Please also be aware that a model is dynamic in both its specifications and calibration. The specifications, those cost elements that comprise the model, may change from time to time based upon research and market conditions. As you may discover, the dollar rates, or calibrations, contained here most likely are different from the current model in use. The model used in this exercise is as follows:

Building RCN = [(Base Rate + \sum ABRV_n) * Effective Area * Size Adjustment + \sum AFRV_n] * (MV₀ * MV₂ * ... * MV_n)

Where:

RCN = Replacement Cost New
Base Rate = \$ rate based on use code
ABRV = Additive Base Rate Variables
Effective Area = Adjusted SF area of improvement
Size Adjustment = Adjustment factor for deviation from base size
AFRV = Additive Flat Rate Variables
MV = Multiplicative Variables

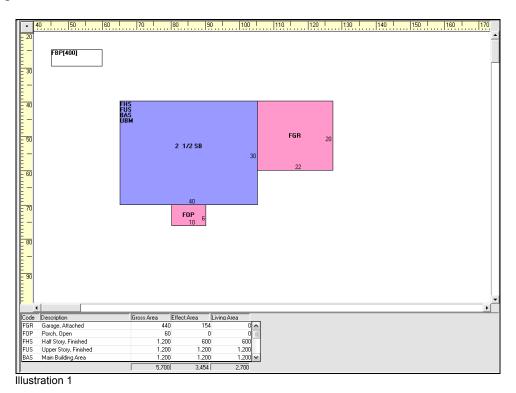

Several items will be helpful while examining the features of the cost model and they are collected as Appendix "A" of this document. You will need to refer to them often during this exercise. They include the following:

- Sample home's Property Record Card (PRC)
- Cost.dat printout of the sample home
- 2007 CAMA Residential Construction Valuation Guideline

1. First, let's illustrate the calculation of the Effective Area of our sample home.

Building RCN = [(Base Rate +
$$\sum$$
 ABRV_n) * Effective Area * Size Adjustment + \sum AFRV_n] * (MV₀ * MV₂ * ... * MV_n)

Illustration 1 shows the CAMA sketch of the sample home we'll be using throughout this exercise.

It is described as a 2½ story single-family detached residence, with basement. It is brick veneer, frame construction with a two-car garage and small porch across the front. The bottom of the sketch screen in CAMA provides the information about the sizes of the various areas of the house.

	_		$\overline{}$	
Code	Description	Gross Area	Effect.Area	Living Area
FGR	Garage, Attached	440	154	, (
FOP	Porch, Open	60	0	0
FHS	Half Story, Finished	1,200	600	600
FUS	Upper Story, Finished	1,200	1,200	1,200
BAS	Main Building Area	1,200	1,200	1,200
UBM	Basement, Unfinished	1,200	300	0
FBP	Basement, Finished, Partn	400		2 0
		5,700	3,454	2,700

The Effective Area is comprised of the totals of the base area (Main Building Area @ 1,200 SF), the finished second floor area (Upper Story, Finished @ 1,200 SF), the adjusted area of the finished half story (Half Story, Finished @ 50% of 1200 SF), the adjusted area of the garage (Garage, Attached @ 35% of 440 SF), and the adjusted area of the unfinished basement (Basement, Unfinished @ 30% of 1,200 SF).

The adjustments to the finished half story, garage and unfinished basement take into account these areas are not as expensive as the finished main building area. For example, if the base rate for the finished main building area is \$100/SF, the rate for the garage area may only be \$35/SF. The RCN value of the garage would be calculated as follows:

RCN of Garage = \$15,400 or (440 SF * \$35)

Another way to state the same situation is to adjust the size of the garage to 40% of its measured size and then multiply the resulting, *or effective*, size by the base rate of \$100/SF:

RCN of Garage = \$15,400 or [(440 * .35) * \$100]

Both methods arrive at the same value for the garage. The first method is more intuitive and easier to explain to taxpayers as it adjusts for the differences in costs for the various areas. The second method again provides the same results but is much easier to model and calculate within a CAMA system, thus the effective area calculations shown here represent the methodology employed in the Vision[©] CAMA system.

Let's take a moment to examine the treatment of the basement in this house. The house has a full-sized basement comprised of 1,200 SF. In addition, the basement contains a finished area (400 SF), and the balance as unfinished. Illustration 3 shows the contribution of the unfinished portion to the effective area calculation. However, notice that the finished portion of the basement is not included in the effective area calculations. The value attributed to this finished area is accounted for as an Additive Flat Rate Variable later in the valuation model. The reason for this methodology is to ensure that the effective area is not erroneously overstated by the amount of any finished area in the basement.

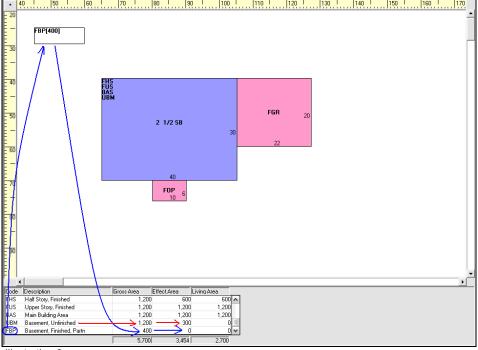

Illustration 3

Finally, the Gross Area shown in Illustration 2 is the total unadjusted size of all the areas that are a part of, and attached to, the home. The Living Area is the unadjusted size of the actual finished living area of the home.

With the inclusion of the Effective Area calculation, our cost model now looks like this:

```
Building RCN = [(Base Rate + \sum ABRV<sub>n</sub>) * 3,454 * Size Adjustment Effective Area + \sum AFRV<sub>n</sub>] * (MV<sub>0</sub> * MV<sub>2</sub> * ... * MV<sub>n</sub>)
```

2. Next, let's look at the selection of the Base Rate for the sample home.

```
Building RCN = [(Base Rate + \sum ABRV_n) * Effective Area * Size Adjustment + <math>\sum AFRV_n] * (MV_0 * MV_2 * ... * MV_n)
```

The Base Rate is the dollar rate per square foot used in the valuation model that is derived from market analysis and selected based on the Use Code of the building. Our sample home is a "Use Code 012 - Detached", corresponding to a Residential-Detached—Single Family residence. The Base Rate is automatically selected by the CAMA system and the appropriate base rate for the sample home is \$ 149.27. Now the cost model looks like this:

```
Building RCN = [(\$149.27 + \sum ABRV_n) * 3,454 * Size Adjustment Base Rate Effective Area + <math>\sum AFRV_n] * (MV_0 * MV_2 * ... * MV_n)
```

3. The Base Rate of the home is just the start of the valuation process and it will be further modified as more specific features about the home are taken into consideration. Let's look at the first of two types of modifications that will affect the Base Rate, the Additive Base Rate Variables (ABRV).

```
Building RCN = [(Base Rate + \sum ABRV_n) * Effective Area * Size Adjustment + \sum AFRV_n] * (MV<sub>0</sub> * MV<sub>2</sub> * ... * MV<sub>n</sub>)
```

Additive Base Rate Variables represent a variety of features found in residential improvements. For example, the value for air conditioning and floor covering are such features. The typical characteristic of these ABRVs is that the features are usually an integral part, and therefore an integral cost, of the whole house. As such, the value of the particular ABRV is added to the Base Rate. Each ABRV incrementally increases the Base Rate by its own square foot rate. So therefore, the $\sum ABRV_n$ literally means the sum of all the rates for individual features are added to the Base Rate.

Highlighted in Illustration 4 are all the fields in the Construction Detail CAMA screen that can modify the selected Base Rate as ABRVs.

Construction	Construction Detail - Residential

Illustration 4

The Cost.dat sheet of our sample home lists each ABRV under the heading Base Rate Adjustments as follows:

```
**************Base Rate Adjustments**************************

AIR CONDITIONING Y (Yes) = 1.8 + BaseRate

EXTERIOR WALL 15 (Face Brick) = 3.95 + BaseRate

FLOOR COVER 11 (Hardwood/Carp) = 4.67 + BaseRate

ROOF COVER 3 (Shingle) = .68 + BaseRate
```

The sum, Σ , is \$11.10 (1.80+3.95+4.67+0.68). This will be added to the Base Rate of \$149.27 to give a modified Base Rate of \$160.37.

Our model now looks like this:

```
Building RCN = [ ( $149.27 + $11.10) * 3,454 * Size Adjustment

Base Rate \sum ABRV_n Effective Area

+ \sum AFRV_n] * (MV<sub>0</sub> * MV<sub>2</sub> * ... * MV<sub>n</sub>)
```

4. Next, let us turn our attention to the second type of modification to the Base Rate - the Size Adjustment.

```
Building RCN = [(Base Rate + \sum ABRV<sub>n</sub>) * Effective Area * Size Adjustment + \sum AFRV<sub>n</sub>] * (MV<sub>0</sub> * MV<sub>2</sub> * ... * MV<sub>n</sub>)
```

The Size Adjustment modifies the Base Rate to account for the size difference between the "standard size" for the "typical" house in the model and the actual size of the sample house. The "standard" size of 1,800 SF for the "typical" house, consisting of a 2-story frame residence, is used as the basis for establishing the initial Base Rates used in CAMA. The adjustment in the Base Rate allows the proper square foot rate to be applied to a house based on its size. It is reasonable to expect that as a house becomes larger than typical, the rate per square foot would decrease and conversely, if the house were smaller than typical, the rate would be higher. This Size Adjustment variable is the component in the model that adjusts for this situation. Our sample home's Size Adjustment is 0.93906 as listed on the Cost.dat sheet. Now our Base Rate is calculated to be \$150.60 ((149.27+11.10) * 0.93906).

Because the adjustment is less than 1.00, it would be proper to conclude that our sample home is larger than the typical 2-story home in the District of Columbia. Had the sample home been smaller than 1,800 SF, the Size Adjustment would have been greater than 1.00. The use of size adjustments eliminates the need for the traditional cost tables based on size.

The cost model continues to grow, and now looks like this:

```
Building RCN = [ ($149.27 + $11.10) * 3,454 * 0.93906
Base Rate \sum ABRV_n Effective Area Size Adjustment + \sum AFRV_n] * (MV<sub>0</sub> * MV<sub>2</sub> * ... * MV<sub>n</sub>)
```

5. We are finished establishing the Base Rate for our sample home and now turn to the Additive Flat Rate Variables (AFRV). This portion of the cost model is relatively straightforward. The individual Additive Flat Rate Variables are summed and the added to the product of the previous calculations.

```
Building RCN = [(Base Rate + \sum ABRV<sub>n</sub>) * Effective Area * Size Adjustment + \sum AFRV<sub>n</sub>] * (MV<sub>0</sub> * MV<sub>2</sub> * ... * MV<sub>n</sub>)
```

Here is where we make allowances for individual extra features contained in the sample house. Illustration 5 shows some of those features that constitute Additive Flat Rate Variables in the cost model:

Construction	Construction Detail - Residential					
Value Source: C Living Area/GFA Primary Occ: 012 Effective Area Structure Class: R Percent Goo		a: 3,454	Regression: 0 Income: 0 RCNLD: 626,350

Illustration 5

Unlike the Additive Base Rate Variables (ABRV) described earlier, most of these features are not an integral portion of the whole house, but stand alone, so to speak. Examples include such items as fireplaces, extra bathrooms, and extra kitchens. Again, as with other variables in the cost model, the values of these features are derived from market analysis.

Our sample home has several Additive Flat Rate Variables (AFRVs), including additional bathrooms and a fireplace. The cost for one full bath and one kitchen is always included in the original base rate. Any bathrooms or kitchens over and above the first are accounted for as AFRVs.

The value of an additive flat rate variable is calculated by multiplying the number of "units" by the dollar rate per unit. For example, illustration 5 shows our sample home also has two half baths. The AFRV for the half baths is \$21,440 (2 "units" X \$10,720 per unit) as shown in a portion of the Cost.dat file below.

Also included in the AFRVs are the partitioned finished basement and the small open porch on the front of the house. Recall that in illustration 3, neither of these areas was included in the calculation of the effective area of the house, therefore, their valuations are included here, as AFRVs.

The partitioned finished basement is calculated to be \$18,000. In this case, "units", the gross square footage of 400 SF (shown in the sketch area of the record), are multiplied by the rate of \$45 per SF. The open porch is calculated in a similar manner.

The sum, Σ , is \$63,341 (16,000+21,440+7,100+18,000+801) that will be added to the product of the previous portions of the cost formula.

The cost model is almost finished for our sample home, and now looks like this:

```
Building RCN = [ ($149.27 + $11.10) * 3,454 * 0.93906
Base Rate \sum ABRV_n Effective Area Size Adjustment + $63,341] * (MV<sub>0</sub> * MV<sub>2</sub> * ... * MV<sub>n</sub>)
\sum AFRV_n
```

6. The last portion of the cost model used to calculate the RCN are the multiplicative variables (MV).

```
Building RCN = [(Base Rate + \sum ABRV<sub>n</sub>) * Effective Area * Size Adjustment + \sum AFRV<sub>n</sub>] * (\frac{MV_0 * MV_2 * ... * MV_n}{MV_0})
```

This portion of the formula can have the largest influence on the cost model. Each multiplicative variable modifies *all* of the cost data that has preceded it. These variables modify the Base Rate, the sum of all the increases to the Base Rate (Σ ABRV_n), the Size Adjustment, and the sum of all the Flat Rate Variables (Σ AFRV_n). This is where such important characteristics as the building grade, building condition, remodeling, and location factors have their impact.

The sample home is graded "Above Average - 4", and consequently has a 1.10 multiplicative factor. This one variable, grade, is going to increase the RCN value of the sample home by 10%. Grade can have a sizable impact on the final value of the building. For example, a "Superior - 8" increases the final rate by 48% over that of an "Average Quality - 3" house.

The condition of the building is also accounted for by the multiplicative variables. The interior, exterior and overall conditions of our sample home are each "Good" and the corresponding multiplicative variable for each is 4.8%. The level of condition may be different for each of the three variables and therefore the coefficients may be different. Please refer to the 2007 CAMA Residential Construction Valuation Guideline --RPAD for these and all other coefficients used in the valuation model.

Just as construction grade has a significant impact on the final value of a house, so does condition. For example, a house in overall "Poor" condition throughout will have its value <u>reduced</u> by 20.6%, whereas a house in excellent condition throughout will have its value <u>increased</u> by 10.5%. That's a range of over 31%.

Illustration "6" shows a portion of the features that constitute the multiplicative variables in the cost model:

Illustration 6

Another important multiplicative variable, Remodel Type, takes into account whether or not the house has been remodeled and to what extent. In addition, the age of the remodel factors into the amount of adjustment applied by this multiplicative variable.

Our sample home was remodeled in 2001. The portion of the CAMA record that captures this information is shown in Illustration 7 below.

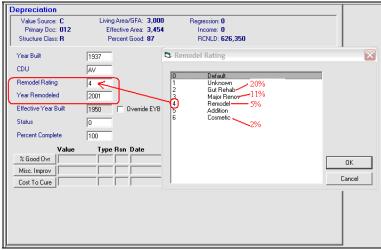

Illustration 7

Obviously, a "Gut Rehab" would increase the value of property more than "Cosmetic" changes, and the coefficients listed in the above illustration demonstrate this. Our sample home was remodeled in 2001, indicating that the MV should be five percent. Five percent would be the correct amount if the remodel occurred in 2005, but it actually occurred in 2001, four years earlier. The CAMA model takes into consideration how long ago a remodel occurred and reduces its impact, as it becomes older. The rate of reduction of the MV is five percent per year. After twenty years, a remodel has no affect on value. In this example, our sample home's remodel occurred four years ago and thus the MV is reduced by twenty percent to 4.0% (5%*.80).

The last multiplicative variable, "Sub-Neighborhood Adj A", is the local neighborhood multiplier established within the particular neighborhood where the sample home is located. This variable is going to lower the RCN value of the sample home by 6.3%. The "Sub-Neighborhood Adj" reflects the market-derived fact that location is a very significant factor in the value of real estate. Two otherwise identical homes can have a substantial difference in value based on their locations.

The variables for our sample home are summarized in the Cost.dat file as follows:

Each MV is multiplied together to determine the combined, or overall, MV. The sample home's MV is 1.2338132 (1.048*1.048*1.1*1.048*1.04*.937).

7. Finally, the Building RCN model is complete and contains the specific data of the sample home used in this demonstration. The market-derived cost model for the sample home is as follow:

```
Building RCN = [(Base Rate + \sum ABRV<sub>n</sub>) * Effective Area * Size $719,947 = [($149.27 + $11.10 ) * 3,454 *.93906 Adjustment + \sum AFRV<sub>n</sub>] * (MV<sub>0</sub> * MV<sub>2</sub> * ... * MV<sub>n</sub>) + $63,341 ] * (1.2338132 )
```

The Cost.dat file shows a summary of the same information.

```

Adjusted Base Rate: 150.6

RCN = ((150.6 * 3454) + 63341) * 1.23381334499738

RCN: 719947

The replacement cost new for our sample home is \$719,947. There is still one thing left to address before we turn our attention to depreciation. Our sample home has a built-in sauna in the basement. This item was not costed as a component of the sample home, but rather as a Special Building Feature, with its own unit price of \$12,680. Also, note that the depreciation applied to the Special Building Features is identical to the amount applied to the main building. See illustration 6 below.

We now know the total replacement cost new (RCN) of our sample home, including the sauna, is \$ 733,197 (\$719,947 + \$13,250).

If the sample home were brand new, we'd be finished, but it was actually built in 1937.

Next, we need to address accrued depreciation . . .

Depreciation

Depreciation is defined as a loss in the upper limits of value from all sources. Typically, three types of depreciation can affect real estate - physical deterioration, functional obsolescence and economic obsolescence. This next portion of the demonstration will illustrate how Vision[©] calculates the amount of depreciation accrued to our sample home.

Several terms come into use when discussing depreciation in CAMA. They are defined as follows:

- Actual Age: The mathematical difference between the Base Year and the actual year the improvement was built to completion.
- Actual Year Built (AYB): The earliest time the main portion of the building was built. It is not affected by subsequent construction.
- Base Year: The year, usually the current year, that the depreciation table is calibrated, such that the age of a building built during the base year would be 0 years old.
- <u>Depreciation Table</u>: A market-driven table that lists the amount of depreciation corresponding to an Effective Year Built and the Base Year predicated upon a specific economic life.
- <u>Effective Age</u>: The mathematical difference, in years, between the Base Year and the Effective Year Built.
- Effective Year Built (EYB): The calculated or apparent year, that
 an improvement was built that is most often more recent than
 AYB. The EYB is determined by the condition and quality of the
 improvement. Subsequent renovation, additions, upgrades and
 the like, extend an improvements remaining economic life and
 therefore cause the EYB to be closer to the Base Year than the AYB.
- <u>Percent Good</u>: The mathematical difference between 100 percent and the percent of depreciation. (100% - depreciation %) = percent good

The RCN model used above indicated that our sample home has an RNC of \$733,197. As stated earlier, the home was built in 1937 so there should be some depreciation to deduct from the RCN. We'll uses a five-step process to depreciate improvements:

- 1. Calculate the Actual Age of the improvement
- 2. Determine the Effective Age of the improvement
- 3. Determine the improvement's Effective Year Built
- 4. Look-up Percent Good corresponding to EYB on depreciation table
- 5. Apply selected depreciation to RCN to determine RCNLD

- 1. Our first step is to calculate the Actual Age of our sample home. As you are aware, a valuation is always qualified as of a specific date. For ad valorem purposes in the District of Columbia, the valuation date is January 1 immediately preceding the tax year. In our example, the tax year is 2007; therefore, the valuation date is January 1, 2006. This date is also significant in terms of the depreciation accrued to improvements. In the past, the nature of triennial assessments required that base years within a Tri-Group remain unchanged for a period of three years. Now, however, with the return to annual assessments, the base year coincides with the valuation date. The Base Year is used to determine the Actual Age of the sample home. In this case, the sample home's Actual Age is 69 years (2006-1937).
- 2. The next step is to determine the sample home's Effective Age. Effective Age may or may not represent actual or chronological age. The premise is simple but the application can be confusing. If a home is built and never maintained (painting, re-roof, etc.) or remodeled, the home would quickly depreciate from physical deterioration. The CAMA system would depreciate the home at the fastest rate possible based on the selected Depreciation Table. For example, CAMA uses a 75-year Economic Life Depreciation Table for residential property. If the home were left to rot, the Effective Age would most likely be the same as the Actual Age.

Let's say the owners of our sample home have completely neglected their property from the time it was built in 1937 to the present. Their home would have an effective age of 69 years as indicated on the Depreciation Table below:

			=					
Depreciation Table				44	11	89	1962	
	- - - -			1	45	11	89	1961
		Year			46	11	89	1960

17	6	94	1989	-	7.5	4.0		1936
18	6	94	1988	_	/5	16	84	1931
Ilustration	1		1000					

The Actual Year Built (1937) and the Effective Year Built (1937) would be the same and consequently the Effective Age is 70 years. Moving across the table,

we see that a home with an EYB of 1937 has 15 percent depreciation and therefore is 85 Percent Good (100%-15%). If the RCN of our sample home is \$733,197, the depreciated value, RCNLD, is only \$623,217 (733,197* 0.85).

Note: The depreciation table moves in 5-year periods towards its end; this explains the apparent inconsistencies in 70 years v. 69 years. The Cost.dat file represents the actual numbers used in calculations.

The situation described above rarely, if ever, occurs in the market. People do maintain and renovate their homes and in doing so, extend the home's useful or remaining economic life. As homeowners repair roofs, paint siding, replace windows and furnaces, they *prolong* the life of the home and consequently *decrease* its Effective Age.

Along with the actual age of the sample home, the illustration below shows which variables within CAMA affect the calculation of effective year built.

Construction	Deta	ail - Residential			
		Living Area/GF/ Effective Are		Regression: 0 Income: 0

Illustration 2

All of the features or variables dealing with depreciation, highlighted in Illustration 2 are multiplicative variables. As such, they are multiplied one by the other and then the Actual Age is multiplied by the product of the MVs. Below is the portion of the Cost.dat file that summaries these MV for our sample home.

```
*************Effective Age Adjustments**************

BATH STYLE 2 (Semi-Modern) = .95 * Age

EFF AGE GRADE 40 (Good Quality) = .95 * Age

KITCHEN STYLE 2 (Semi-Modern) = .9 * Age
```

The product of each of these MV adjustments is calculated to be 0.81225 (0.95 * 0.95 * 0.9). This product is then multiplied by the Actual Age to calculate the Effective Age. Recall our sample home's Actual Age is 69 years. The Effective Age is calculated to be 56 years (69 * 0.81225). Instead of CAMA using 69 chronological years to calculated depreciation, it will use 56 years. Below is a portion of the Cost.dat file that shows these calculations.

Effective Age = 69 * .81225 Effective Age: 56 Percent Good = 87

RCNLD: 626350

- 3. We're almost finished. Knowing the Effective Age makes the calculation of the Effective Year Built for our sample home very simple. The Effective Year Built is 1950 (2006 56).
- **4.** Having established the Effective Year Built, we look up 1950 on the *75-Year Economic Life Depreciation Table* and find that the Percent Good is 87% for that year. See Illustration 3 below.

Depreciation Table Base Year 2006					44	11	89	1962
					45	11	89	1961
					46	11	89	1960

7	4	96	1999	l	50	13	07	1000
- 8	1	96	1998	_	51	13	07	1949

5. The last step in the process is to simply multiple the RCN by 0.87 and we have RCN LD. The depreciated, market-derived cost approach value of the sample home used in this demonstration is \$ 626,350.

Some closing comments regarding depreciation are in order. Recall from the outset that we defined depreciation as a loss in value resulting from physical deterioration, functional and/or economic obsolescence. The demonstration above dealt only with depreciation attributed to the physical deterioration of the sample home. This, by far, is the most common type of depreciation that exists in residential property. However, occasions may require additional depreciation because of excessive physical deterioration, functional and/or economic obsolescence. One must use caution when invoking these types of depreciation. The market must support any decision regarding the extent of these adjustments. Below illustrates our sample home with an additional ten percent economic obsolescence. A gas station was built across the street from the home, and a recent sale of the next-door neighbor's house showed the impact of this situation.

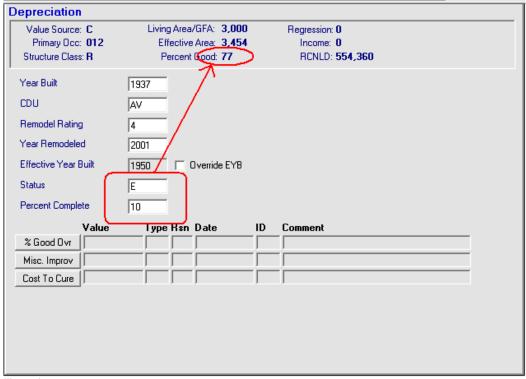

Illustration 4

The actual mechanics of adjusting depreciation for functional or economic obsolescence within CAMA are briefly discussed below. If the situation occurs, seek guidance from your supervisor and/or CAMA manager.

Illustration 5 shows the portion of the CAMA screen used to allow for additional depreciation. It is not necessary to make adjustments in the "CDU" field or to override the EYB field. Nor is it necessary to enter information on the lower 1/3 of the screen. The "Status" and "Percent Complete" fields are the only two fields that are utilized to account for additional depreciation.

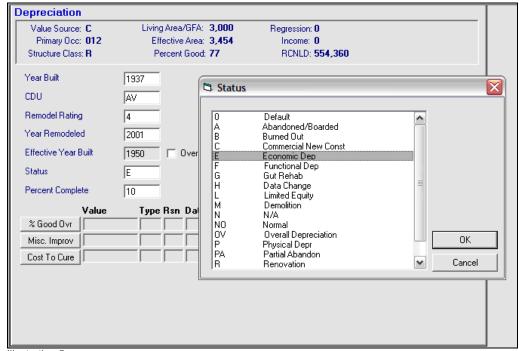

Illustration 5

The "Status" field's pick-list is expanded in Illustration 6 to show only those types of items that have a direct affect on depreciation and the nature of the affect. Notice that only a limited number of Status Codes are functional within CAMA and their affect on depreciation is either to *replace* the existing amount in the "% Good" field or *decrease* the "% Good." The corresponding numeric amount that will affect the "% Good" is entered in the field called "Percent Complete." Please note that the field name "Percent Complete" is somewhat erroneous because the word "Complete" has no meaning in this context. This is the field that you will enter the amount to either decrease the existing "% Good" or replace the existing "% Good," based on the Status Code selected.

	Status Code	es
Code	Description	Affect on % Good
0	Default	NONE
Α	Abandoned/Boarded	NONE
В	Burned Out	NONE
C	Commercial New Const	REPLACE
E	Economic Dep	DECREASE
F	Functional Dep	DECREASE
G	Gut Rehab	NUNE
Н	Data Change	NONE
L	Limited Equity	NONE
М	Demolition	NONE
N	N/A	NONE
NO	Normal	NONE
OV	Overall Depreciation	REPLACE
P	Physical Depr	DECREASE
PA	Partial Abandon	NUNE
R	Renovation	NONE
T	Order of Taking	NONE
V	Vacant	NONE

Illustration 6

Recall our example of the gas station. The Percent Complete field has "10" as it's value. Based on the "E" Status Code, we know that the original depreciation will increase by ten percent resulting in a decrease in Percent Good to 77% (87-10).

Another comment regarding depreciation concerns the impact that the quality of design, material and workmanship have on depreciation. The grade assigned to a home obviously makes a considerable difference in the final RCN, but it also plays a substantial part in determining the amount of depreciation accrued to the home. It is easy to understand that if all other things were equal, a home built with better material and workmanship would age better than one with poorer materials and workmanship. The higher quality the home the more slowly it will deteriorate. Conversely, a shoddily built home will age more quickly than the average home.

Lot Valuation

Now that we've calculated RCN in the first section and the amount of depreciation in the second section, we know the value of our improvements from the formula RCN-LD to be \$639,030.

Next let's turn our attention to the final portion of the process – land or lot valuation. There are several aspects or characteristics to land that affect its value. Needless to say the old adage "Location, Location, Location!" is certainly true, but beyond that there are considerations for such things as lot size, shape, frontage, topography, view, restrictions and the like that influence the final value of land.

Let's once again return to our sample home and examine the details on the PRC to get our first look at the lot valuation.

							1	AND LIN	E VA	LUATION	SECTI	10N			·	
B:	# Occ	Description	Zone	Frontage	Depth	Units	S.I.	I. Factor	LT	Price	Size Adj	Site Rating	Adjustments	Special Use	Notes	Land Value
1	012	Residential Detached Single Fa				6,000 Si	P	1.00		63.14	0.8630	1.0	00T:80%	V:0	Poor topo in back; River view	375,060

Illustration 1

Notice that the detail tells us the lot size, the price per unit, and any adjustments that affect the lot. The model used to calculate the value of lots in CAMA is as follows:

Lot Value = [Lot Size *((Base Rate * Size Adjustment) + ∑ Dollar Adjustments) * ∑ Percent Adjustments]

The formula represents the following steps:

- 1. Determine the base rate for the particular neighborhood where the lot is located and multiply that rate by the 'size adjustment factor';
- 2. Next, add the adjusted rate in step one to the sum of all dollar amount adjustments;
- 3. Next, multiply the results by the lot size;
- 4. Lastly, multiply that result by the product of all percentage adjustments.

Most of this activity can be seen in the Land.Dat file in Appendix A of this document. You may wish to refer to it as we go through this exercise.

Let's expand the discussion and follow the steps of the process to explain the lot valuation of our sample home in more detail.

1. "Determine the base rate for the particular neighborhood where the lot is located and multiply that rate by the 'size adjustment factor'."

The residential base land rates are different for each (sub)neighborhood in the District. Each year, the current base rates are updated in CAMA and published in the *Appraiser Reference Materials*. In addition to the base rates, the base lot sizes and size curves are included. Our property is located in Chevy Chase, and below shows the portion of the land rate table for that neighborhood:

NBHD	Base Lot Size	Base Rate	Base Lot Value	Size Curve
11 A	5,000 sf	\$73.16	\$365,800	LG 1

Illustration 2

The base rate for our property is \$ 73.16 per sf.

The size adjustment factors are also incorporated in CAMA. These factors make allowances for lots whose sizes differ from the standard "base" size for the lots in that particular (sub)neighborhood. Recall that as the size or area of a building or lot increases, the dollar rate per unit typically goes down from the base rate, and conversely, the dollar rate typically increases over the base rate when the area or size is smaller than the standard base rate.

Recall that our lot is 6,000 sf in size. The table states that the Base Lot Size is 5,000, so a size adjustment will be necessary. Intuitively, one would expect that the size adjustment would be less than 100% because the actual lot is larger than the base size lot. CAMA contains the algorithms to calculate the proper size adjustment. Essentially, it determines which "land size curve" is to be used as the basis for determining the adjustment, then it mathematically interpolates and extrapolates the factor from the particular size table associated with the curve based on the amount of difference between the standard size and the actual size.

In the case of our sample home, the size curve is LG 1. This curve is one of the four curves existing in CAMA and it is effect on rates is the lowest of the curves. Based on the difference between the base size and the actual size of the lot, CAMA has selected a factor of 0.863 as the adjustment. If the lot were smaller, say 4,000, sf the selected factor would have been 1.198.

So, to finish step 1, we multiply the (sub)neighborhood base land rate by the calculated size adjustment factor to arrive at a size adjusted rate of \$ 63.14 (\$73.16 * 0.863).

2. "Next, add the adjusted rate in step one to the sum of all dollar amount adjustments."

If there are any dollar-amount adjustments to the rate, this is the time to make the them. For example, you may choose to lower the rate by \$10 per sf on a particular lot in a neighborhood because it is on a busy street corner. In our example, the rate is increased by \$15 per sf because the property has an excellent view of the river not enjoyed by the other lots in the neighborhood. This adjustment increases the rate to \$78.14 (\$63.14 + \$15.00).

Use caution when making any adjustments to the calculated rates. If adjustments are warranted, seek guidance from your supervisor or CAMA manager.

3. "Next, multiply the resulting rate by the lot size."

This is an easy step. The land value at this point is \$468,822 (\$78.14 * 6,000).

4. "Lastly, multiply that result by the product of all percentage adjustments."

As before, here's where we can reflect adjustment to the lot for such things as topography, view, shape irregularity, and the like. There may be an easement across the back of the lot that affects value. Again be certain that the adjustment is peculiar to just the subject or a few lots in the (sub)neighborhood, otherwise the condition would have been already accounted for in the calculations done by the multiple regression analysis process that generated the original base rates, size curves and standard lot sizes.

Our sample lot had a steep drop-off across the back that the appraiser accounted for by adjusting the final rate by 80 percent. This is the last calculation to determine the subject property's lot value. The final value of our lot is \$ 375,060 (468,822 * 0.80).

The illustrations below summarize much of the information discussed in this land valuation exercise. Illustration 3 shows a portion of the data entry screen in Vision[©] CAMA and the second, illustration 4, is the Land.dat file with selected information highlighted.

```

Illustration 4

Some Final Thoughts

We have introduced you to some of the most elementary aspects of property valuation using the District's Vision® CAMA system. We have developed the RCN of a fictitious home, reduced its value by the accrued depreciation and finally added the land value component to complete the appraisal. This guideline is merely a small window, a first step, in the complex field of CAMA mass appraisal. A CAMA system robust enough to appraise 180,000 different properties will necessarily be comprehensive and complex. As you explore and utilize the program make certain that you fully understand the ramifications and results of your actions. Your supervisor and/or CAMA manager will always be available to assist you.

Vision Commercial CAMA Valuation Process

he market-derived cost approach to the valuation of real estate follows the generic formula of **Market Value = ((RCN LD) + land value)**, where **RCN** is Replacement Cost New of the improvements and **LD** means Less Depreciation. When properly developed and calibrated, this approach is a reliable indicator of market value especially suited to mass-appraisal CAMA systems.

The following exercise will attempt to illustrate how the Vision[©] CAMA system utilized by the District of Columbia, calculates values using the above model. The first portion will illustrate the development of the Replacement Cost New of a small commercial building, and the last portion will show the steps involved in determining the amount of depreciation that has accrued to the building. Land valuation is not discussed in this exercise.

Replacement Cost New

The Vision© CAMA system arrives at a RCN value for commercial properties based on a market-calibrated hybrid cost model. The hybrid nature of the model simply means that the model employs both additive and multiplicative variables in its design and specification. The nature of the model will become clearer as we proceed through this exercise. Please also be aware that a model is dynamic in both its specifications and calibration. The specifications, those cost elements that comprise the model, may change from time to time based upon research and market conditions. The calibration of the model is primarily derived from information provided by the Marshall and Swift Valuation Service, a company that provides building cost data necessary for real estate cost valuations and is widely considered the authority on the cost approach to valuation. As you may discover, the dollar rates, or calibrations, contained here most likely are different from the current model in use. The model used in this exercise is as follows:

```
Building RCN = [Section<sub>1</sub> (Base Rate * Effective Area * Size Adjustment) * (MV_1 * MV_2 * ... * MV_n)] + [Section<sub>n</sub> (Base Rate * Effective Area * Size Adjustment) * (MV_1 * MV_2 * ... * MV_n)] + [\sum Special Building Features]
```

Where:

RCN = Replacement Cost New
Base Rate = \$ rate based on occupancy (use) code and construction class
Section_n = Each separate building or section of building
Effective Area = Adjusted SF area of improvement
Size Adjustment = Adjustment factor for deviation from base size
MV = Multiplicative Variables

Several items will be helpful while examining the features of the cost model and they are collected as Appendix "A" of this document. You will need to refer to them often during this exercise. They include the following:

- Sample building's Property Record Card (PRC)
- Cost.dat printout of the sample building
- Depreciation Schedule
- 2007 CAMA Construction Valuation Guideline Commercial

The commercial building designed for this exercise is typical of a small commercial property in the District. It consists of a one-story full service restaurant and an adjoining two-story building. The two-story section consists of a package goods store and a small apartment on the second floor. The building is of good quality and is constructed of brick veneer over concrete block. For this exercise, the building has been logically sectioned into two sections. Section 1 covers the restaurant and Section 2 covers the package goods/apartment portion.

Below shows the Construction Detail in the CAMA record of the building. The first illustration depicts Section 1 – the restaurant and the second represents Section 2 – the package goods store and apartment.

Illustration 3 shows the CAMA sketch of the sample building we'll be using throughout this exercise.

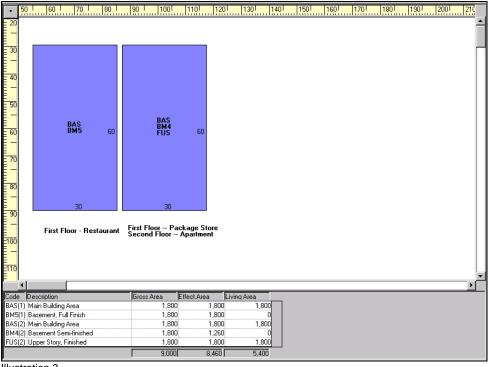

Illustration 3

The bottom of the sketch screen in CAMA provides the information about the sizes of the different areas that comprise the two sections of the building. Each section is denoted as (1) or (2) under the Code column.

Code Description	Gross Area	Effect, Area	Living Area	
BAS(1) Main Building Area	1,800	1,800	1,800	
BM5(1) Basement, Full Finish	1,800	1,800	0	
BAS(2) Main Building Area	1,800	1,800	1,800	
BM4(2) Basement Semi-finished	1,800	1,260	0	
FUS(2) Upper Story, Finished	1,800	1,800	1,800	
	9,000	8,460	5,400	

Illustration 4

1. First, let's illustrate the calculation of the Effective Area of our sample building's first section, the restaurant.

Building RCN = [Section₁ (Base Rate * Effective Area * Size Adjustment) *
$$(MV_0 * MV_2 * ... * MV_n)$$
] + [Section_n (Base Rate * Effective Area * Size Adjustment) * $(MV_0 * MV_2 * ... * MV_n)$] + [\sum Special Building Features]

Code	Description	Gross Area	Effect,Area	Living Area	
BAS(1)	Main Building Area	1,800	1,800	1,800	
BM5(1)	Basement, Full Finish	1,800	1,800	0	
BAS(2)	Main Building Area	1,800	1,800	1,800	
BM4(2)	Basement Semi-finished	1,800	1,260	0	
FUS(2)	Upper Story, Finished	1,800	1,800	1,800	
		9,000	8,460	5,400	

Illustration 5

The Effective Area is comprised of the totals of the Bas(1) Main Building Area @ 1,800 SF and the BM5(1) Basement, Full Finish @ 1,800 SF for a total of 3,600 SF.

The second section's Effective Area is calculated in the same manner.

Code Description	Gross Area	Effect.Area	Living Area
BAS(1) Main Building Area	1,800	1,800	1,800
BM5(1) Basement, Full Finish	1,800	1,800	0
BAS(2) Main Building Area	1,800	1,800	1,800
BM4(2) Basement Semi-finished	1,800	1,260	0
FUS(2) Upper Story, Finished	1,800	1,800	1,800
	9,000	8,460	5,400

Illustration 6

BAS(2) Main Building Area, BM4 (2)Basement Semi-finished, and FUS (2) Upper Story, Finished total 4,860 SF. The adjustment to the semi-finished basement takes into account this area is not as expensive as the finished main building area. For example, if the base rate for the finished main building area is \$100/SF, the rate for the semi-finished basement area may only be \$70/SF. The RCN value of the basement would be calculated as follows:

RCN of Basement = \$126,000 or (1800 SF * \$70)

Another way to state the same situation is to adjust the size of the basement to 70% of its measured size and then multiply the resulting, *or effective*, size by the base rate of \$100/SF:

```
RCN of Basement = $126,000 or [(1800 * .70) * $100]
```

Both methods arrive at the same value for the basement. The first method is more intuitive and easier to explain to taxpayers as it adjusts for the differences in costs for the various areas. The second method again provides the same results but is much easier to model and calculate within a CAMA system, thus the effective area calculations shown here represent the methodology employed in the Vision[®] CAMA system.

The Gross Area shown in Illustration 2 is the total unadjusted size of all the areas that are a part of the building. The Living Area is more properly called "Gross Floor Area" and is the unadjusted size of the actual finished floor area above grade in the building.

With the inclusion of the Effective Area calculation, our cost model now looks like this:

```
Building RCN = [Section<sub>1</sub> (Base Rate * 3600 * Size Adjustment) * Effective Area  (MV_0 * MV_2 * ... * MV_n)] + \\ [Section_n (Base Rate * 4860 * Size Adjustment) * \\ Effective Area \\ (MV_0 * MV_2 * ... * MV_n)] + \\ [\sum Special Building Features]
```

2. Next, let's look at the selection of the Base Rate for the sample building. There will be two rates because there are two different sections. Each section's RCN will be independently calculated.

```
Building RCN = [Section<sub>1</sub> (Base Rate * Effective Area * Size Adjustment) * (MV_0 * MV_2 * ... * MV_n)] + [Section<sub>n</sub> (Base Rate * Effective Area * Size Adjustment) * (MV_0 * MV_2 * ... * MV_n)] + [\sum Special Building Features]
```

The Base Rate is the dollar rate per square foot used in the valuation model that is derived from tables within the CAMA system. It is selected based on the building's Building Occupancy (Use) Code and Construction Class. Our sample's first section is a "45-Store-Restaurant" constructed as a Class "C", concrete block/brick building. Based on this information, the Base Rate of \$ 109.26 is automatically selected.

The second section, "49-Commercial Retail-Misc.", also constructed as a Class "C", concrete block/brick building, has a Base Rate of \$75.62.

With the inclusion of the selected Base Rates, our model now looks like this:

```
Building RCN = [Section<sub>1</sub> ( $109.26 * 3600 * Size Adjustment) * Base Rate Effective Area (MV_0 * MV_2 * ... * MV_n)] + [Section<sub>n</sub> ( $75.62 * 4860 * Size Adjustment) * Base Rate Effective Area (MV_0 * MV_2 * ... * MV_n)] + [\sum Special Building Features]
```

3. Next, let us turn our attention to a modification to the Base Rate - the Size Adjustment.

```
Building RCN = [Section<sub>1</sub> (Base Rate * Effective Area * Size Adjustment) * (MV_0 * MV_2 * ... * MV_n)] + [Section<sub>n</sub> (Base Rate * Effective Area * Size Adjustment) * (MV_0 * MV_2 * ... * MV_n)] + [\sum Special Building Features]
```

The Size Adjustment modifies the Base Rate to account for the size difference between the "standard size" for the "typical" building of a particular occupancy type and the actual size of the sample building. The comparison is based on the building's "gross floor area." The "standard" size of 5,000 square feet for the "typical" restaurant is used as the basis for establishing the initial Base Rates used in Section 1 of this appraisal. The "standard" size of 4,000 square feet for the "typical" retail-misc. is used as the basis for establishing the initial Base Rates used in Section 2.

The adjustment in the Base Rate allows the proper square foot rate to be applied to a building based on its size. It is reasonable to expect that as a building becomes larger than typical, the rate per square foot would decrease and conversely, if the building were smaller than typical, the rate would be higher. The Size Adjustment variable is the component in the model that adjusts for this situation. Our sample building's size, the "gross floor area," is the total area of both sections, 5,400 square feet. Our building is only slightly larger than the standard size of 5,000 square feet. The Size Adjustment is 0.98825. Now our Adjusted Base Rate is calculated to be \$107.98(109.26 * 0.98825) for Section 1 and \$74.73 (75.62 * 0.98825) for Section 2 of our example.

Because the adjustment is less than 1.00, it would be proper to conclude that our sample building is larger than the typical building of its type in the District of Columbia. Our sample building was compared to the larger of the two "standard" sizes, 5,000 square feet. Had the sample building been smaller than 5,000

square feet, the Size Adjustment would have been greater than 1.00. The use of size adjustments eliminates the need for the traditional cost tables based on size.

The cost model continues to grow, and now looks like this:

```
Building RCN = [Section<sub>1</sub> ( $109.26 * 3600 * 0.98825) * Base Rate Effective Area Size Adjustment (MV_0 * MV_2 * ... * MV_n)] + [Section<sub>n</sub> ( $75.62 * 4860 * 0.98825) * Base Rate Effective Area Size Adjustment <math>(MV_0 * MV_2 * ... * MV_n)] + [\sum Special Building Features]
```

4. The next portion of the cost model used to calculate the RCN are the multiplicative variables (MV).

```
Building RCN = [Section<sub>1</sub> (Base Rate * Effective Area * Size Adjustment) * (MV_0 * MV_2 * ... * MV_n)] + [Section<sub>n</sub> (Base Rate * Effective Area * Size Adjustment) * (MV_0 * MV_2 * ... * MV_n)] + [\Sigma Special Building Features]
```

This portion of the formula can have the largest influence on the cost model. Each multiplicative variable modifies *all* of the cost data that has preceded it. These variables modify the Base Rate and Size Adjustment. This is where such important characteristics as the CDU (condition, desirability, utility), building grade, local cost multipliers, Neighborhood and Sub Neighborhood location factors have their impact.

The CDU, or Condition Desirability Utility, is the first of our multiplicative variables. This variable is used to account for a property's general overall physical condition and to a lesser extent the desirability and the utility of the property. Our sample building has been listed as "Good" and the appropriate multiplicative variable is 1.15. Stated a different way, the "Good" CDU will increase the RCN of our building by 15%. This one variable, CDU, can have a profound impact on the RCN of a building. The range can increase the RCN for an "Excellent" building by 35% all the way down to a 90% reduction in RNC for an "Unsound" building.

The sample building is graded "Good Quality - 4", and consequently has a 1.12 multiplicative variable. This one variable, grade, is going to increase the RCN value of the sample building by 12%. Another MV, "DC Local Multiplier C" modifies costs to account for the small additional costs incurred in construction of "C" class buildings in the in the DC area. The other multiplicative variable, "COMM NBHD 9", is the local neighborhood multiplier established for the particular neighborhood where the sample building is located. This variable is

going to increase the RCN value of the sample building by 10%. The "COMM NBHD" adjustment reflects the market-derived fact that location is a very significant factor in the value of real estate. Two otherwise identical buildings can have a substantial difference in value based on their locations.

These four variables are summarized in the Cost.dat file as follows:

Each MV is multiplied together to determine the combined, or overall, MV. The sample building's MV is 1.501808 (1.15 * 1.12 * 1.06 * 1.1).

5. Except for the Special Building Features, our RCN model is complete and contains the specific data for the sample building used in this demonstration. The RCN cost model for the sample building is as follow:

```
Building RCN = [Section<sub>1</sub> ($109.26 * 3600 * 0.98825) *

Base Rate Effective Area Size Adjustment

( 1.501808 )] +

Multiplicative Variables

[Section<sub>n</sub> ($75.62 * 4860 * 0.98825) *

Base Rate Effective Area Size Adjustment

( 1.501808 )] +

Multiplicative Variables

[∑ Special Building Features]
```

The RCN for Section 1, the restaurant is \$ 583,795 (\$109.26 * 3600 * 0.98825 * 1.501808). The package goods store's RCN is \$423,520 (\$75.62 * 4860 * 0.98825 * 1.501808).

The Cost.dat file shows a summary of the same information as follows:

Section #1

Base Rate: 109.265 Size Adjustment: .98825 Effective Area: 3600

Adjusted Base Rate = (109.26 + 0) * .98825

Adjusted Base Rate: 107.98

RCN = ((107.98 * 3600) + 0) * 1.501808

RCN: 583795 Section #2 Base Rate: 75.62

Size Adjustment: .98825 Effective Area: 4860

Adjusted Base Rate = (75.62 + 0) * .98825

Adjusted Base Rate: 74.73

RCN = ((74.73 * 4860) + 0) * 1.501808

RCN: 545438

So far, the RCN of the building is \$ 1,129,233 (583,795+545,438). We still have Special Features to add to complete the cost model.

6. The Special Features component is the last portion of the cost model. This is the place where such things as sprinklers and HVAC systems are accounted for and valued in the building.

```
Building RCN = [Section<sub>1</sub> (Base Rate * Effective Area * Size Adjustment) *
                   (MV_0 * MV_2 * ... * MV_n)] +
                   [Section<sub>n</sub> (Base Rate * Effective Area * Size Adjustment) *
                    (MV_0 * MV_2 * ... * MV_n)] +
                   [ Special Building Features]
```

Take a look at illustration 7. Here we see that both sections are sprinklered and heated and cooled with a complete HVAC system. Both of these Special Building features are calculated based on the size, in square feet, of the area affected. Their value is determined by the size, dollar rate and quality grade for each feature. Finally, the Special Building Features are depreciated at the same rate as the main buildings.

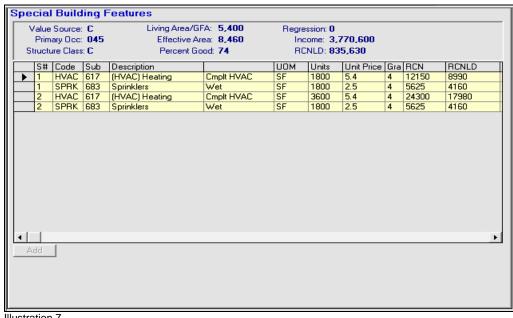

Illustration 7

Illustration 8 shows the data-entry screen, as it would look if we were to add an elevator to the building.

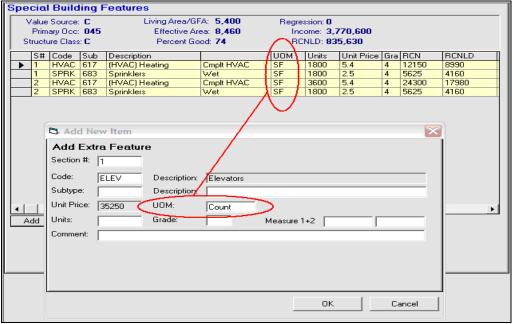

Illustration 8

Note that this extra feature's UOM (unit of measurement) is by count and not SF. For each count, the unit price is \$35,250. Be sure that the UOM is proper for the individual special feature included in the building.

The total RCN of the Special Feature in this sample is \$ 47,700 (Σ Special Building Features = 12,150 + 5,625 + 24,300 + 5,625).

We now know the total replacement cost new (RCN) of our sample building, including Special Features, is \$ 1,176,933 (\$1,129,233 + \$47,700).

```
$1,176,933 =
                                                    3600
                      [Section<sub>1</sub> ( $109.26
                                                                    0.98825) *
Building RCN
                                 Base Rate
                                              Effective Area Size Adjustment
                         1.501808 )] +
                       Multiplicative Variables
                    [Section<sub>n</sub> ( $75.62
                                                  4860 *
                                                                 0.98825) *
                                 Base Rate Effective Area Size Adjustment
                         1.501808
                                      )] +
                       Multiplicative Variables
                    [ $47,700 ]
                   [ \( \sumsymbol{\subset} \) Special Building Features]
```

If the sample building were brand new, we'd be finished, but it was actually built in 1953.

Next, we need to address accrued depreciation . . .

Depreciation

Depreciation is defined as a loss in the upper limits of value from all sources. Typically, three types of depreciation can affect real estate - physical deterioration, functional obsolescence and economic obsolescence. This next portion of the demonstration will illustrate how Vision[®] calculates the amount of depreciation accrued to our sample building.

Several terms come into use when discussing depreciation in CAMA. They are defined as follows:

- Actual Age: The mathematical difference between the Base Year and the actual year the improvement was built to completion.
- Actual Year Built (AYB): The earliest time the main portion of the building was built. It is not affected by subsequent construction.
- Base Year: The year, usually the current year, that the depreciation table is calibrated, such that the age of a building built during the base year would be 0 years old.
- <u>Depreciation Table</u>: A market-driven table that lists the amount of depreciation corresponding to an Effective Year Built and the Base Year predicated upon a specific economic life.
- <u>Economic Life</u>: The useful life span for a structure based on its occupancy (use) code and its construction class.
- <u>Effective Age</u>: The mathematical difference, in years, between the Base Year and the Effective Year Built.
- Effective Year Built (EYB): The calculated or apparent year, that an improvement was built that is most often more recent than AYB. The EYB is determined by the condition and quality of the improvement. Subsequent renovation, additions, upgrades and the like, extend an improvements remaining economic life and therefore cause the EYB to be closer to the Base Year than the AYB.
- <u>Percent Good</u>: The mathematical difference between 100 percent and the percent of depreciation. (100% - depreciation %) = percent good

The RCN model used above indicated that our sample building has an RNC of \$1,176,933. As stated earlier, the building was built in 1953, so there should be some depreciation to deduct from the RCN. We'll use a seven-step process to depreciate the improvements:

- 1. Calculate the Actual Age of the improvement.
- 2. Determine the Effective Age of the improvement.
- 3. Determine the improvement's Effective Year Built.
- 4. Look-up Depreciation corresponding to EYB on depreciation table.
- 5. If required, modify the depreciation by the amount given for obsolescence.
- 6. Apply final depreciation to RCN to determine RCN-LD.
- 1. Our first step is to calculate the Actual Age of our sample building. As you are aware, a valuation is always qualified as of a specific date. For ad valorem purposes in the District of Columbia, the valuation date is January 1 immediately preceding the tax year. In our example, the tax year is 2007, therefore the valuation date is January 1, 2006. This date is also significant in terms of the depreciation accrued to improvements. In the past, the nature of triennial assessments required that base years within a Tri-Group remain unchanged for a period of three years. Now, however, with the return to annual assessments, the base year coincides with the valuation date. The base year is used to determine the Actual Age of the sample building. In this case, the Actual Age of the sample building is 53 years (2006-1953).
- 2. The next step is to determine the sample building's Effective Age. Effective Age may or may not represent actual or chronological age. The premise is simple but the application can be confusing. If a building is built and never maintained (painting, re-roof, etc.) or remodeled, the building would quickly depreciate from physical deterioration. The CAMA system would depreciate the building at the fastest rate possible based on the selected Depreciation Table. For example, our building has an economic life of sixty years. If the building were left to rot, the Effective Age would most likely be the same as the Actual Age.

Let's say the owners of our sample building have completely neglected their property from the time it was built in 1953 to the present. Their building would have an effective age of 53 years as indicated on the Depreciation Table below:

			Econom	ic Life Depre	ciation Tables			
Base	Year	2006						
			70 Year Economic	Life	60 Year Economi	ic Life	50 Year Econmi	c Life
Age of	<i>f</i>	Effective	Percent of	Percent	Percent of	Percent	Percent of	Percent
Building	g	Year Built	Depreciation	Good	Depreciation	Good	Depreciation	Good
	0	2006	0	100	0	100	0	11
	1	2005	0	100	0	100	0	1
	2	2004	1	99	1	99	2	
	3	2003	1	99	1	99	2	
	48	1958	46	54	58	43	77	:
	49	1957	47	53	59	41	78	
	50	1956	49	51	61	39	82	
	51	1955	51	49	64	36		
	52	1051	52	10	05	95		
	53	1953	54	46	68	33		
	54	1952	55	45	89	91	,	
	55	1951	57	43	71	29		
	56	1950	58	42	73	28		
	57	1949	60	40	75	25		
	58	1948	61	39	76	24		
	59	1947	63	37	79	21		
	60	1946	64	36	80	20		
	61	1945	65	35				
	62	1944	67	33				
	63	1943	68	32				
	64	1942	70	30				
	65	1941	71	29				
	70	1940	76	24				
	75	1932	80	20				

Illustration 9

The Actual Year Built (1953) and the Effective Year Built (1953) would be the same and consequently the Effective Age would be 53 years. Moving across the table, we see that a building with an EYB of 1953 has 68 percent depreciation and therefore is 32 Percent Good (100%-68%). If the RCN of our sample building is \$1,176,933, the depreciated value, RCN-LD, is only \$ 376,619 (1,176,933* 0.32).

The situation described above rarely, if ever, occurs in the market. People do maintain and renovate their buildings and in doing so, extend the building's useful or remaining economic life. As building owners repair roofs, paint siding, replace windows and furnaces, they *prolong* the life of the building and consequently *decrease* its Effective Age.

A recent building remodel, renovation or rehabilitation will go a long way to extend its useful life. As the useful life is extended, the Effective Age is reduced and therefore the Effective Year Built is more recent than the building's Actual Year Built.

Our sample building had a major renovation done in 1998. The portion of the CAMA record that captures this information is shown in Illustration 10 below.

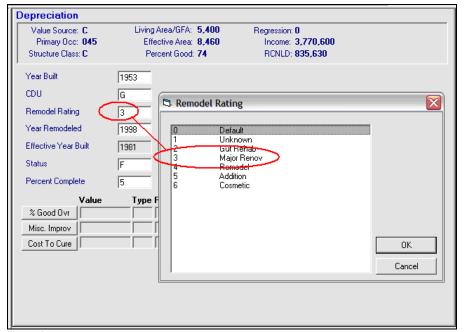

Illustration 10

Two factors come together to determine the impact a remodel has on the amount of depreciation calculated for the building – the Remodel Rating and the Year Remodeled. How extensive the remodel is and how recently it has occurred combines to determine its overall affect on its effective year built, and in turn, the building's depreciation. A brand-new gut rehab would substantially decrease the effective age of a building much more so than an older remodel. Conversely, an older remodel may have little or no affect on the depreciation.

We'll see the significance of that renovation in a moment, but first, back to our sample building's Effective Age calculation.

The construction class of the building also affects the calculation of Effective Age. It is only natural that an "A" class structure would have a longer economic life than a "D" class building (recall the story of the three little pigs). The Structure Class Age Factor makes allowance for this situation by reducing the effective age of an "A" class building by more than, say, a "D" building. As an example, CAMA reduces the effective age by 20% for "A" buildings, 15% for "B" structures, 10% on "C" buildings, and no adjustment for the "D" class buildings.

The features or variables dealing with the effective age calculation are multiplicative variables. As such, they are multiplied one by the other and then the Actual Age is multiplied by the product of the MVs. Below is the portion of the Cost.dat file that summaries these MV for our sample building.

The product of each of these MV adjustments is calculated to be 0.46575 (0.45 * 0.90 * 1.15). This product is then multiplied by the Actual Age to calculate the Effective Age. Recall our sample building's Actual Age is 53 years. The Effective Age is calculated to be 24 years (53 * 0.42525). Instead of CAMA using 53 chronological years to calculated depreciation, it will use 24 years, based on the building's quality and renovation. The portion of the Cost.dat file that illustrates this information is below:

Actual Year Built: 1953 Effective Age = 53 * .46575 Effective Age: 24 Percent Good = 74 RCNLD:835630

Back to our renovation, the 1998 major renovation done to the building reduced the effective age to 51.75% (Rehab Factor 3 = .45 * Rehab Year = 1.15) of the 53 years of actual age, resulting in an effective age of 27 years old. What impact on the effective age would there be if just a small remodel occurred in 1990? We would expect the effective age not to shorten, or decrease, as much. Let's see what happens.

As you know, CAMA has many calibrated variables associated with all of the calculations it makes to determine the RCN and calculate depreciation. Again, the two variables that come into play here are the Rehab Factor and the Rehab Year. We've just seen the values of those variables were with regard to the recent major renovation example. For the 1990 remodel the values are: Rehab Factor 4= 0.55 and Rehab Year = 1.15. This combination will reduce the effective age to 63.25% (0.55 * 1.15) of the 53 years of actual age, as a result, making the effective age now 34 years old.

The difference between the two scenarios is seven years. Without doing all math, the difference in the appraised value as a result an effective age of 31 years verses 24 years is about \$100,000 on a building with a RCN of \$1,769,933. The proper documentation of remodel activity is significant when arriving at proper appraised values.

- 3. We're almost finished. Knowing the Effective Age makes the calculation of the Effective Year Built for our sample building very simple. The Effective Year Built is 1982 (2006 24).
- **4.** Having established the Effective Year Built, we look up 1982 on the *60* Year Economic Life Depreciation Table and find that the Depreciation is 20% for that year. See Illustration 11.

		Econom	ic Life Depre	ciation Tables

31	1975	23	77	29	71	38	
90	4074	0.4	70	00	70	40	

You may notice that there is a conflict between the Cost.dat file and the depreciation table with regards to "Percent Good." The Cost.dat file report that our building's percent good is 74, whereas the depreciation table says it's 80. The explanation is addressed in step 5, dealing with obsolescence and direct adjustments to depreciation, not effective year built calculations.

5. If the assessor notes any obsolesce, this is where it is addressed. Recall from the outset that we defined depreciation as a loss in value resulting from physical deterioration, functional and/or economic obsolescence. The demonstration up to this point has dealt only with depreciation attributed to the physical deterioration of the sample building. This, by far, is the most common type of depreciation that exists in commercial property. However, occasions may require additional depreciation because of excessive physical deterioration, functional and/or economic obsolescence. One must use caution when invoking these types of depreciation. The market must support any decision regarding the extent of these adjustments.

Our sample building is suffering from a small amount of functional obsolescence. The assessor has noted that the interior design of the building contains many support columns interrupting the efficient use of the floor space. As a result, the restaurant has a few less tables and the package goods store does not have a good aisle layout. Consequently, it is appropriate to allow for a small amount of functional obsolescence – five percent.

Illustration 12 shows the results of this additional allowance for functional obsolescence. Whereas the depreciation table in illustration 3 shows the percent good for 20 years at 80%, by subtracting the 5% attributed to functional obsolescence, we are left with 74% (rounding error) as the percent good for our building. This matches the figure shown in the Cost.dat file.

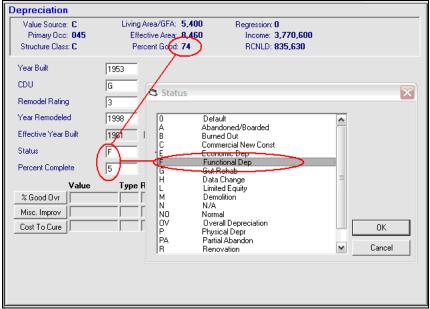

Illustration 12

The actual mechanics of adjusting depreciation for functional or economic obsolescence within CAMA are briefly discussed below. If the situation occurs, seek guidance from your supervisor and/or CAMA manager.

The "Status" field's pick-list is expanded in Illustration 13 to show only those types of items that have a direct affect on depreciation and the nature of the affect. Notice that only a limited number of Status Codes are functional within CAMA and their affect on depreciation is either to *replace* the existing amount in the "% Good" field or *decrease* the "% Good." The corresponding numeric amount that will affect the "% Good" is entered in the field called "Percent Complete." Please note that the field name "Percent Complete" is somewhat erroneous because the word "Complete" has no meaning in this context. This is the field that you will enter the amount to either decrease the existing "% Good" or replace the existing "% Good", based on the Status Code selected.

	Status Code:	s

Illustration 13

6. The last step in the process is to simply multiple the RCN by 0.74 and we have RCN LD of the building. Knowing the total RCN of our sample building is \$1,176,933, the RCN LD is \$870,920 (1,176,933 * 0.74). Below is a portion of the Property Record Card that illustrates this information.

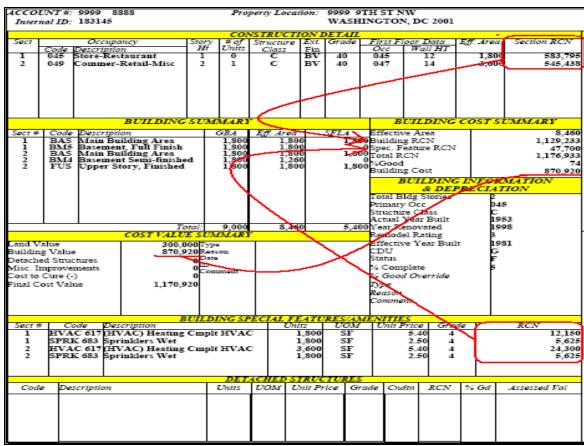

Illustration 14

Conclusion

This exercise has been prepared to assist the commercial assessor understand some of the concepts, features and techniques employed by the Vision® CAMA system in arriving at a cost approach to valuation of commercial properties in the District of Columbia. It does not serve as an exhaustive training manual. Any specific questions regarding the features and operations of this CAMA should be directed to your supervisor or the CAMA manager.

Vision® CAMA Income Approach Valuation Process

he income approach to the valuation of real property follows the generic formula of Market Value = NOI/Capitalization Rate, where NOI is the net operating income of the property and the Capitalization Rate is a market-derived overall direct capitalization rate. When properly developed and calibrated, this approach is a reliable indicator of market value of income producing properties within a mass-appraisal CAMA system.

The following exercise will attempt to illustrate how the Vision[©] CAMA system utilized by the District of Columbia calculates values using the above model. The first section will illustrate the traditional development of a market value estimate for a typical apartment building. This example will serve to provide a practical foundation for understanding the concepts of the income approach to valuation as well as an understanding of the major components of the Vision[©] CAMA methodology. The second section will illustrate the actual CAMA valuation of the apartment building described in the first section.

Income Approach to Value

An understanding of the income capitalization approach to value is essential in order to utilize the Vision® CAMA system's income model. Of the three traditional approaches to value (cost, market, income), the income approach is most often the appropriate approach when appraising property owned for it's ability to produce income to the owner. An owner anticipates future income production and the income approach quantify the present value of the income derived from the ownership of the property. There are several varieties or forms of the income approach used to quantify or convert income into an estimate of value. The most widely used approach is direct capitalization. Direct capitalization involves converting one year's stabilized net operating income into an estimate of value in one direct step using an appropriate rate. The direct capitalization method is rooted in the market. The rate used to convert income into value represents the relationship between value and income through the following formula:

To determine an estimate of value, divide the income by the rate. The income is the net operating income (NOI) and the rate is the direct capitalization rate. For example, if a property generates an NOI of \$50,000 per year and the market-derived capitalization rate is 8 percent, the indicated value would be \$625,000 (\$50,000/.08).

Where do these two numbers come from? The first number, NOI, is determined by a combination of things. First, the income and expenses of the particular property are analyzed and "re-constructed" to produce the NOI. Re-constructing simply means that we analyze the income and more particularly the expenses to ensure that we have a true understanding and estimate of the amount of net operating income annually produced by the property. Oftentimes an income report will detail some expenses not directly associated with the property. For example, the debt service of a loan on the property may be subtracted from the gross income. This is not a proper expense as it is a function of the owner's financing and not an operating expense of the property. Another example may be a large "expense" taken against gross income that should be more properly spread over several years, or capitalized. Expense ratios are calculated for the various categories of expenses.

Another source for determining the NOI of a property is the analysis of many other similar properties for their income levels and expense levels or ratios. If the subject property's income and expenses are typical for similar properties, the actual NOI of the property becomes the amount to be capitalized by the rate. If, on the other hand, the property exhibits unusual income or expenses based on comparison of the ratios, some actual amounts of income or expenses may be substituted with the amounts represented by more typical ratios. The goal is to establish the typical level of NOI that a prudent investor would anticipate deriving from the property each year.

Where does the rate come from? The rate is the overall direct capitalization rate. This is the rate for the overall property used to convert a single year's income into an indication of value of the overall property using the IRV formula shown above. The rate is derived through sales analysis. Ideally, where arms-length sales of similar properties occur and the income and expense data are well known, a direct capitalization rate can be derived using the IRV formula. For example, suppose the subject property is office building and a similar office building recently sold for \$750,000. The reconstructed income and expense analysis indicated that at the time of sale the property was producing an annual net operating income of \$60,000. Using the IRV formula, the capitalization rate of the property was 8 percent (\$60,000/\$750,000). Reliable capitalization rates are the result of the analysis of many sales of income producing properties.

The following illustration is an example of a reconstructed income and expense statement for our sample property. The property, Breakaway South, is a high-rise apartment complex consisting of a one eight story concrete block building. The building has 164 rental units, a management office, laundry facility and on-site surface parking. It is located in the area of Saint Elizabeth's in SE

Washington, DC. We'll use this property both here and in the example within Vision[®] CAMA in the second part of this tutorial.

Breakaway South Apartments - December 31, 2006-					
Potential Gross Income Vacancy & Collection Loss (4%) Miscellaneous Income (laundry) Effective Gross Income Expenses	\$1,419,600 - 56,784 <u>+ 54,000</u> \$1,416,816

Total Expenses (64%)	\$906,762				
Net Operating Income (36%) Capitalization Rate: Indicated Market Value	\$510,054 6.0% \$8,500,900				

Illustration 1

As you examine the statement, you'll notice a few terms we have not discussed. The **potential gross income** is defined as the maximum amount of income the property can produce if fully rented at market rent before any expenses are deducted. There will always be some amount to deduct from the potential gross income in the form of **vacancy** and **collection loss**. Even if the property is fully leased, the appraiser must take some vacancy allowance to acknowledge tenant

turn-over and inevitable vacancies. It is unrealistic not to allow for some vacancy. Collection loss is that amount deducted from the potential gross income for nonpayment of rent.

In addition to rent, a property may have other sources of income. This **miscellaneous income** can come from such sources as an on-site laundry facility, furniture rental, community room rentals, and the like.

When an amount for vacancy and collection loss is subtracted, and an amount for miscellaneous income is added to the gross potential income, the result is the **effective gross income** of the property. Expenses are subtracted from, and expense ratios are calculated based upon, the effective gross income.

Expenses usually fall into two categories: **operating expenses** and **reserves for replacement**. Sometimes operating expenses may be further divided between variable and fixed expenses. Operating expenses are those legitimate expenses necessary to support the property's ability to produce effective gross income. The sample shows some of the more typical expenses incurred by an apartment building. Notice the calculation of the expense ratios mentioned earlier. As an example, the expense ratio for management is eleven percent of the effective gross income (\$155,850/\$1,416,816). These actual ratios are compared to typical ratios to see if any expenses are out of the ordinary.

Reserves for replacements are a category of expenses that are designed to set aside funds for long lived items that periodically need to be replaced. The amount of the expense is based on the item's economic life and the estimated cost to replace it in the future. Let's say that appliances must be replaced every five years at an estimated cost of \$1,728 per unit. With 164 units, we need to accumulate \$ 283,392 over a five year period. Charging \$56,673 per year to the reserves for replacement expense allows us to set aside enough money to replace the appliances according to the five year schedule. It is always appropriate to set aside reserves for replacements, even though in practice a property may not have done so. This is another aspect to "re-constructing" the income statement.

Subtracting the total expenses from the effective gross income leaves us with the net operating income of the property. The NOI of the property is the "I" in the IRV formula that will be converted to an indication of value using a capitalization rate.

As mentioned earlier, we employ the direct capitalization of income to produce an estimate of value. Again, the capitalization rates are determined by the analysis of sales of similar properties where the NOI is known. Capitalization rates vary between and within different categories of income-producing properties. Extensive analysis is necessary to determine the proper rate to apply to the different properties. For example, a capitalization rate for a high quality office building in a prime location will be lower than a capitalization rate for a lower quality office in a less desirable location. With all other things remaining equal and no unusual externalities, capitalization rates for offices are generally less

than rates for motels or shopping centers. It all harkens back to the level of return the buyer's expect to receive on their investment in commercial real estate. One of their considerations is that the more risk involved with the property, the more return they require thereby raising the capitalization rate resulting in a lower valuation.

We have selected a capitalization rate of 6 percent for our example property. Based on the information we now have available we can estimate the market value of the subject apartment to be \$8,500,900 (\$510,054/0.06).

The above discussion has been presented as a review of the income approach to valuation, more specifically the direct capitalization technique. Included was an example of the valuation of an apartment building. In the next section, we'll again value the same apartment building but conduct the valuation from within the District's CAMA system. Although the work flow may appear different, the underlying IRV formula should generate the same results.

Vision's® CAMA Income Approach to Value

In addition to the market-calibrated cost approach utilized by CAMA to value the residential property in the District, CAMA also has the capability to value commercial property using the more appropriate approach — the income capitalization approach. The discussion in this section will serve to illustrate the manner in which a commercial property, an apartment building, is valued based on the income approach.

To effectively value property, complete and accurate property characteristic must be known. Although the physical characteristics such as wall type, roof type, building style and the like are important, the most important information regarding commercial property subject to the income approach are characteristics of the property dealing with its ability to produce income. In an office building, for example, the gross building area or net leaseable area are important. In hotels and motels the significant measure is the number of rooms available. And in apartment buildings it would be the number and style of the units for rent.

We'll begin our appraisal of Breakaway South by identifying the "mix" of units in the building. The table below represents this information.

The mix of units is as follows:

No. of Bedrooms	1 Bed	2 Bed	3 Bed
No. of Bathrooms	1 Bath	1 Bath	2 Bath
No. of Units	62	76	26

Table 1

From our previous discussion of the income approach, we know that there are three "key" areas having to do with the income approach to value:

- Gross Income
- Vacancy & Expenses
- Capitalization Rate

The illustration below highlights the location of these key areas on the data entry screen within CAMA.

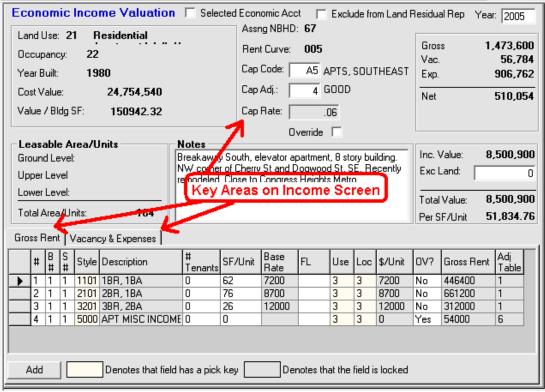

Illustration 2

Gross Rent

Recall we will be appraising the same apartment property from the example in the first section. Let's first turn our attention to the Gross Rent tab on the data entry screen. We'll be entering information about the complex in the Gross Rent table, using one line for each *style* of apartments. By style, we mean the unit of comparison designated for apartment buildings – 1 bed-1 bath, 2 bed w/den-1 bath, 3 bed-2 bath, and the like.

Let's look at the first line of the table:

	Gross Rent Vacancy & Expenses															
1		#	B #	S #	Style	Description	# Tenants	SF/Unit	Base Rate	FL	Use	Loc	\$/Unit	0V?	Gross Rent	Adj Table
Į	•	1	1	1	1101	1BR, 1BA	0	62	7200		3	3	7200	No	446400	1
Ш		Ζ	Т	T	2101	ZBH, IBA	U	/b	8700		3	3	8700	INO	661200	
Г		3	1	1	3201	3BR, 2BA	0	26	12000		3	3	12000	No	312000	1
Γ		4	1	1	5000	APT MISC INCOME	0	0			3	3	0	Yes	54000	6
ľ																

Illustration3

Our first line will account for the 1 bedroom-1 bath units in the complex. The style code "1101" is selected from a pick-list that describes the different styles available for apartments. Please refer to the illustration below for a partial list of Income Style for apartments.

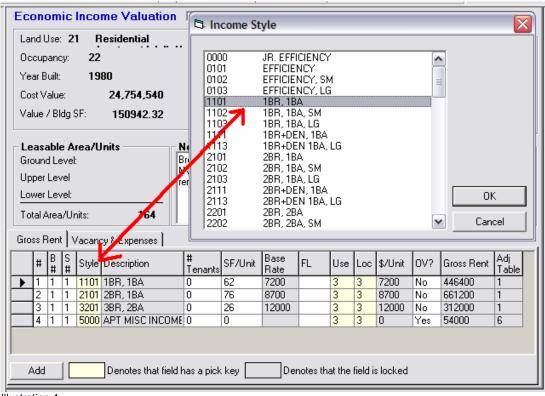

Illustration 4

Recall that there are sixty-two 1BR, 1BA units and that number is recorded in the "SF/Unit" column of the table. In addition to recording the style and number of units, the appraiser may choose to modify the Gross Rent by taking into consideration both the tenant desirability and the location of the apartment. The two columns labeled "Use" and "Loc" account for these adjustments, respectively. The adjustments are percentage increases or decreases to the

Gross Income from the default value of "average." Both the "Use" and "Loc" allow for the same percent adjustment each, as shown in the illustration below.

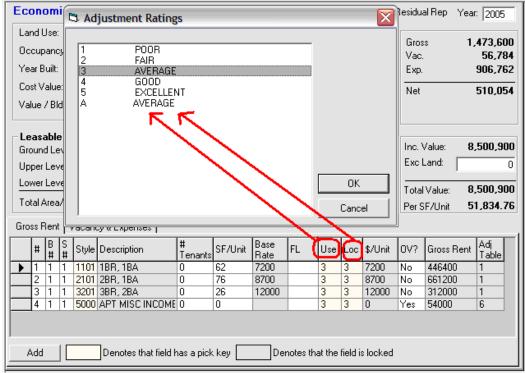

Illustration 5

The amount of adjustment is based on the table below:

Rating	Description	Location	Use
1	POOR	0.8	0.8
2	FAIR	0.9	0.9
3	AVERAGE	1	1
4	GOOD	1.1	1.1
5	EXCELLENT	1.25	1.25
Α	AVERAGE	1	1

Table 2

In our example, we chose not to make any adjustments for location or desirability to any of the apartment units in this property.

The Base Rate shows the annual rent for each unit of the particular style "1101" – 1BR, 1BA. In this example the rent is \$ 600 per month or \$7,200 on an annual basis as shown in the base rate column. This value has been selected from a table in CAMA. The table has been calibrated based upon extensive market analysis of current rents segmented by location and style, throughout the District. Below is an excerpt of a table that illustrates the rents for our particular property.

			COLITHEAST
	Code	Description	SOUTHEAST Monthly Rent
	0000	JR. EFFICIENCY	416
	0101	EFFICIENCY	520
	0102	EFFICIENCY, SM	468
	0103	FFFICIENCY I G	572

	3101	3BR, 1BA	900
	3102	3BR, 1BA, SM	810
	3103	3BR, 1BA, LG	990
	3111	3BR+DEN, 1BA	1150
	3113	3R+DEN 1BA LG	1265
(3201	3BR, 2BA	1000

Table 3

Notice that our subject property is located in the Southeast market. The District of Columbia is divided into nine separate commercial markets for modeling purposes. The market influences within the Southeast are, for example, different from the influences within Central Business District or the Northwest market. Separate rent schedules exist for each separate market.

As we continue with our example, we account for the other two styles of units in a similar manner. At this point, the gross rent has been calculated to be \$1,419,600. But, if you recall from the income and expense statement, the property generated an additional \$54,000 in non-rental income. We need to include this amount to determine to total gross income.

To account for the miscellaneous income, select "5000 APT MISC INCOME" as the style and enter the actual amount directly into the Gross Rent column. We want to be sure to set the "OV?"(override), column to "Yes." By doing so, we ensure that the amount does not get adjusted for vacancy and collection loss discussed in the next section. Typically, only rental income is subjected to vacancy and collection loss. See the illustration below:

ŧ	#	B #	S #	Style	Description	# Tenants		Base Rate	FL	Use	Loc	\$/Unit	0V?	Gross Rent	Adj Table
1	П	1	1	1101	1BR, 1BA	0	62	7200		3	3	7200	No	446400	1
72	2	1	1	2101	2BR, 1BA	0	76	8700		3	3	8700	No	661200	1
	Ц	1	1	2201	200, 204	0	20	12000		3	3	12000	No	212000	1
1 4	1	1	1	5000	APT MISC INCOME	0	0			4	4	0	Yes	54000	6
Add Denotes that field has a pick key Denotes that the field is locked															

Illustration 6

This concludes our discussion of the Gross Rent tab in the CAMA system. We have accounted for all of the rent attributable to the property and concluded that the Gross Rent is the sum of \$ 1,473,600, the same amount as shown on the income and expense sheet from section one. Next, we'll turn to the Vacancy & Expenses portion of the record.

Vacancy and Expenses

Our work in the Vacancy and Expenses tab will be similar to what we did in the Gross Income tab. However, in this table we'll account for four items:

- Vacancy amount
- EGI (Effective Gross Income) calculation
- Expense amount
- NOI (Net Operating Income) calculation

The sum of the NOI calculated here will be the basis for the final valuation using the IRV formula, after selecting a rate. See below:

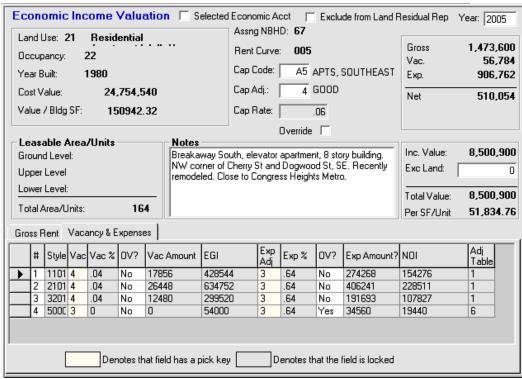

Illustration 7

A Vacancy and Expenses line is automatically created for each style shown on the Gross Rent tab. The values assigned by CAMA are based on the market location of the property and are derived from extensive market analysis. Recall that our apartments are located in the Southeast market. CAMA populates the Vac% column and the Exp% column with the market rates appropriate for Southeast; in this case it would be based on this table:

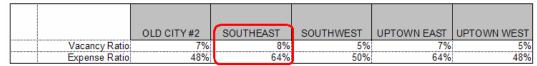

Table 4

You may have noticed that the Vacancy % in the table and on the tab does not agree. We have examined the property and concluded that the vacancy rate should be less than the typical of 8 percent, to reflect the true status of the property. To make this adjustment, change the value in the column named "Vac' to an appropriate number. In this case, the vacancy is "Good", thereby changing the Average, 8 percent to a lesser amount of 4 percent. See the illustration below:

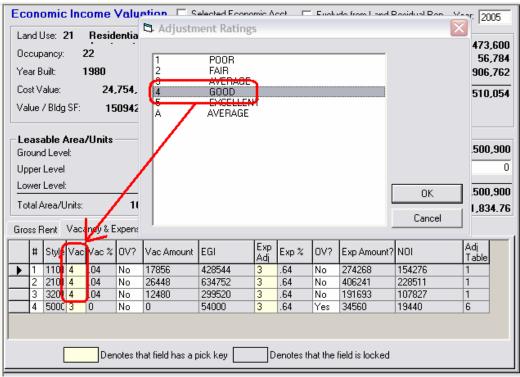

Illustration 8

The amount of adjustment for both vacancy and expense are shown in the table below. Whereas the typical vacancy for the Southeast market area is 8 percent, selecting "Good", modifies the vacancy ratio by appropriate multiplier in the adjustment table. The adjusted amount is 4 percent (0.08 * 0.50).

Rating	Description	Vacancy	Expense
1	POOR	2	1.25
2	FAIR	1.5	1.1
3	AVERAGE	1	1
4	GOOD	0.5	0.9
5	EXCELLENT	0.25	0.75
Α	AVERAGE	1	1

Table 5

By subtracting the vacancy amount calculated here from the Gross Income from the Gross Rent, the result is the EGI, as shown.

The Expense % may be adjusted in a similar manner, but in this case we'll leave it set to the typical percent associated with the Southeast market of sixty-four percent. By subtracting the Exp. Amount from the EGI, we get the NOI of the property. CAMA has calculated the NOI to be \$510,054, identical to our earlier income and expense report.

We're almost done. The last piece of the valuation puzzle is the capitalization rate.

Capitalization Rate

The capitalization rate is assigned to the property based on its market location. Neighborhood 67, Saint Elizabeth's, is located in the Southeast market area.

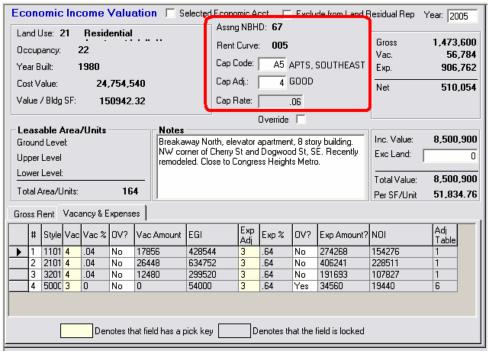

Illustration 9

Capitalization rates may vary across the District based on the class of property (office, retail, apartments, etc.) and its location (market area). The assigned capitalization rate for apartments in the Southeast market is 0.069 or 6.9 percent.

Upon analysis of the property and its income and expenses, an adjustment to the cap rate is warranted. Instead of 'average', we want to adjust the rate down to reflect the property's overall good performance. Its good performance appears to be attributed, in part, to its close location to the hospital and the Congress Heights Metro stop. This adjustment is accomplished by the Cap Rate adjustment dialog box. See below.

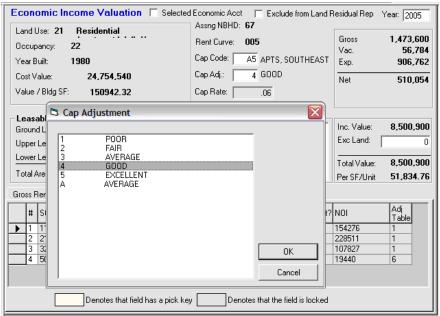

Illustration 10

The typical market capitalization rate was to be 0.069. The adjustment to good changed the rate to 0.060 or 6 percent. This was accomplished by multiplying the assigned rate by the appropriate adjustment factor, in this case 0.87.

Had we determined that the property was inferior and the cap rate needed to be adjusted to "Fair", the resulting rate would have been 0.079 or 7.9 percent. Remember IRV tells us that, all other things being equal, the lower the cap rate the higher the property value and visa versa. The table below shows the capitalization rate adjustment factors.

Cap Rating	Description	Adjustment
1	POOR	1.29
2	FAIR	1.15
3	AVERAGE	1
4	GOOD	0.87
5	EXCELLENT	0.75
Α	AVERAGE	1

Table 6

Valuation

We have finally come to the end of our example and exercise. One simple division remains. Knowing that the NOI is \$510,054 and that the overall direct capitalization rate is 0.06, we can calculate the estimated value of Breakaway South to be \$8,500,900 (\$510,054/0.06). Again, this is identical to the amount estimated in the first section of the exercise. The final results are highlighted below.

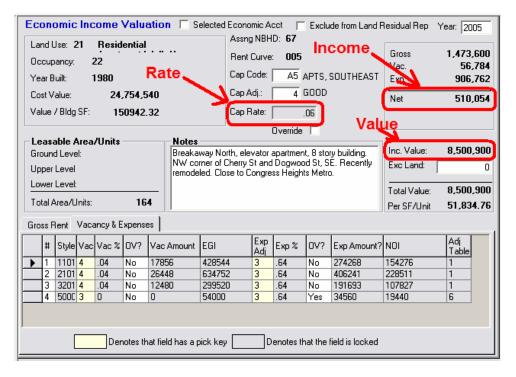

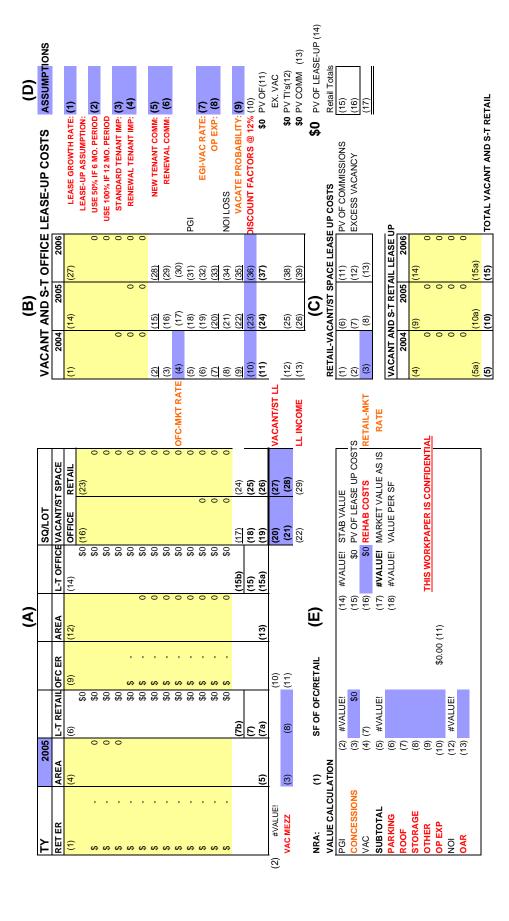

Illustration 11

Some Final Thoughts

We have introduced you to some of the most elementary aspects of property valuation using the District's Vision[®] CAMA system. We have developed the estimated market value of a fictitious apartment complex, utilizing the direct capitalization income approach to value. This guideline is merely a small window, a first step, in the complex field of mass appraisal. A CAMA system robust enough to appraise 184,000 different properties will necessarily be comprehensive and complex. Additionally, an initial valuation generated by CAMA is always subject to the review and approval of a qualified, professional appraiser before it becomes a final value. As you explore and utilize the program make certain that you fully understand the ramifications and results of your actions. Your supervisor and/or CAMA manager will always be available to assist you.

6-14	Retail Leases Scheduled to Expire in 2003	YES Retail Rental Rate X Area X Occ Rate X Leaseup Assumption % X Vacate %
C-15	Total of Retail Leases Scheduled to Expire in 2003	
C-15a	Additional Retail Area from Additional Revenue Worksheet	YES Adds Total Area from Additional Revenue Worksheet Sec H-16

	Description	Calc Calculation
Lease Growth Rate	Selected Yearly Lease Growth Rate	ON
Lease-up Assumption	Used to Estimate Excess Vacancy	ON
Standard Tenant Improvement	T I Cost Applied to New Leasesd Space	ON
Renewal Tenant Improvement	T I Cost Applied to Renewal Leased Space	ON
New Tenant Commission	Leasing Commission Applied to New Leased Space	ON
	Leasing Commission Applied to Renewal Leased Space	ON
D-7 Vacancy Rate	Selected Vacancy Rate to Determine Eff Gross Income	ON
	Expenses Used to Determine NOI Loss for Excess Vacancy	ON
D-9 Vacate Probability	If Tenant is Leaving 100% is Used This Effects Vacancy, TI's & Comm	ON
D-10 Discount Rate	Used to Calculate Discount Factors	ON
D-11 PV of Excess Vacancy	Sum of PV Office Excess Vacancy for 2001-2003	YES Sum of PV office Ex Vac 2001-2003
D-12 PV TI's	Sum of PV of Office TI's for 2001-2003	YES Sum of PV of Office TI's for 2001-2003
	Sum of Office Commissions for 2001-2003	
	Sum of PV of Office Excess Vacancy, TI's & Commissions	
D-15 PV of Commissions	Sum of PV of Retail Commissions for 2001-2003	YES Sum of PV of Retail Commissions for 2001-2003
D-16 Excess Vacancy	Sum of Retail Excess Vacancy for 2001-2003	YES Sum of Retail Excess Vacancy for 2001-2003
D-17 Total PV of Retail	PV of Total Retail Commissions & Retail Excess Vacancy	YES PV of Total Retail Comm & Retail Excess Vacancy
NRA	Total Square Footage of Office and Retail	YES Total of all Square Feet in Section A (Office, Retail, Mezz, Lower Level)
PGI	Potential Office Mezzanine Retail Gross Income	
Concessions	Enter Lease Concessions	ON
Vacancy Rate	Vacancy Percentage	YES Vacancy from Section D
Subtotal	Office and Retail Income Minus	YES PGI-Concessions-Vacancy
Parking	Estimated Parking Income	ON
Roof	Typical Antenna Income	ON
Storage	Storage Income	ON
	Other Income	ON
E-10 Op Expenses	Operating Expenses	
	Operating Expenses Per SQFT	
	Net Operating Income	YES Total Income minus Op Ex
	Selected Capitalization Rate	
	Value before Any Lease-up Costs	
	PV of All Office & Retail Lease-up Cost	YES PV of Off Lease-up Cost + PV of Retail Lease-up Cost
	PV of Rehab Cost, PV of Above or Below Market Rent Difference	
	Total Estimated Market Value	
E-18 Value Per Square Foot	Market Value Per SqFt of NRA	YES Market Value divided by NRA
Long I erm Retail Rent	Continuation from income Worksheet Of Long Term Retail Rents	ON
